Local discontinuous Galerkin methods for the Cahn-Hilliard type equations

Yinhua Xia∗, Yan Xu† and Chi-Wang Shu‡

Abstract

In this paper we develop local discontinuous Galerkin (LDG) methods for the fourth-order nonlinear Cahn-Hilliard equation and system. The energy stability of the LDG methods is proved for the general nonlinear case. Numerical examples for the Cahn-Hilliard equation and the Cahn-Hilliard system in one and two dimensions are presented and the numerical results illustrate the accuracy and capability of the methods.

1 Introduction

In this paper, we consider numerical methods in a bounded domain $\Omega \in \mathbb{R}^d \ (d \leq 3)$ for the Cahn-Hilliard equation

$$u_t = \nabla \cdot \left( b(u) \nabla ( -\gamma \Delta u + \Psi'(u)) \right), \quad (1.1)$$

and the Cahn-Hilliard system

$$\begin{cases} u_t = \nabla \cdot (B(u)\nabla \omega), \\ \omega = -\gamma \Delta u + D\Psi(u), \end{cases} \quad (1.2)$$

where $\{D\Psi(u)\}_{l=1}^m = \frac{\partial \Psi(u)}{\partial u_l}$ and $\gamma$ is a positive constant. Here $b(u)$ is the non-negative diffusion mobility and $\Psi(u)$ is the homogeneous free energy density for the scalar case (1.1). For the system case (1.2), $B(u)$ is the symmetric positive semi-definite mobility matrix and $\Psi(u)$ is the homogeneous free energy density.

We develop a class of local discontinuous Galerkin (LDG) methods for these nonlinear equations. Our proposed scheme is high order accurate, nonlinear stable and flexible for arbitrary $h$ and $p$ adaptivity. The proof of the energy stability of the scheme is given for the general nonlinear solutions.

The Cahn-Hilliard equation was originally propose by Cahn and Hilliard [8] to study the phase separation in binary alloys. The Cahn-Hilliard system was proposed by Morral and Cahn [27] to model three-component alloys. When a single homogeneous system composed of two or three components at high temperature is rapidly cooled to a temperature $\theta$ below the critical temperature $\theta_c$, the phase separation happens. The Cahn-Hilliard equations have been adopted to model many other physical situations, e.g. interface dynamics in multi-phase fluids.

There have been many algorithms developed and simulations performed for the Cahn-Hilliard equations, using finite element methods [2, 3, 4, 6, 7, 15, 16, 17, 20], discontinuous Galerkin methods [9, 21, 31], multi-grid method [23, 24, 25] and finite difference methods [19, 22, 30].

Here we should mention the difference between our LDG method and the discontinuous Galerkin methods in [9, 21, 31]. The discontinuous Galerkin method considered in [9] refers to a discontinuous Galerkin discretization in time, hence is
different from our approach of using a local discontinuous Galerkin discretization for the spatial variables. The discontinuous Galerkin method in [31] used the standard $C^0$ finite element shape functions instead of the discontinuous basis functions in our LDG method which are allowed to be completely discontinuous across element interfaces. In [21], a discontinuous Galerkin method which is in the DG family known as the interior penalty method [1] was developed for the constant mobility case (i.e. $b(u) = \text{constant}$). Stability was proved in [21, 31], but only for the constant mobility case. Our LDG method does not contain mesh dependent stabilization coefficients as in [21]. Moreover, we prove stability for quite general nonlinear cases, for any orders of accuracy on arbitrary triangulations in any space dimension.

The discontinuous Galerkin (DG) method is a class of finite element methods, using discontinuous, piecewise polynomials as the solution and the test space. It was first designed as a method for solving hyperbolic conservation laws containing only first order spatial derivatives, e.g. Reed and Hill [28] for solving linear equations, and Cockburn et al. [12, 11, 10, 13] for solving nonlinear equations. It is difficult to apply the DG method directly to the equations with higher order derivatives. The idea of the LDG method is to rewrite the equations with higher order derivatives into a first order system, then apply the discontinuous Galerkin method on the system. The design of the numerical fluxes is the key ingredient to ensure stability.

The first LDG method was constructed by Cockburn and Shu in [14] for solving nonlinear convection diffusion equations containing second order spatial derivatives. Their work was motivated by the successful numerical experiments of Bassi and Rebay [5] for the compressible Navier-Stokes equations. Yan and Shu developed an LDG method for a general KdV type equation (containing third order spatial derivatives) in [36], and they generalized the LDG method to PDEs with fourth and fifth order spatial derivatives in [37]. Levy, Shu and Yan [26] developed LDG methods for nonlinear dispersive equations that have compactly supported traveling wave solutions, the so-called “compactons”. More recently, Xu and Shu [32, 33, 34, 35] further developed the LDG method to solve many nonlinear wave equations with higher order derivatives, including the general KdV-Burgers type equations, the general fifth-order KdV type equations, the fully nonlinear $K(n,n,n)$ equations, the generalized nonlinear Schrödinger equations, the coupled nonlinear Schrödinger
equations, the Kuramoto-Sivashinsky equations, the Ito-type coupled KdV equations, the Kadomtsev-Petviashvili equation, and the Zakharov-Kuznetsov equation. A common feature of these LDG methods is that stability can be proved for quite general nonlinear cases. DG and LDG methods also have several attractive properties, such as their flexibility for arbitrary $h$ and $p$ adaptivity and their excellent parallel efficiency.

The paper is organized as follows. In Section 2, we present and analyze the local discontinuous Galerkin methods for the Cahn-Hilliard system. In Section 2.1, we review the properties of the Cahn-Hilliard equation and the Cahn-Hilliard system. In Section 2.2, we present the local discontinuous Galerkin methods for the Cahn-Hilliard system. We prove a theoretical result of the energy stability for the nonlinear case. Section 3 contains numerical results for the nonlinear problems which include the Cahn-Hilliard equation and the Cahn-Hilliard system for one-dimensional and two-dimensional cases. The numerical results demonstrate the accuracy and capability of the methods. Concluding remarks are given in Section 4.

2 The LDG method for the Cahn-Hilliard system

2.1 Properties of the Cahn-Hilliard system

We consider the model for phase separation of a multi-component alloy with $N \geq 2$ components in bounded domain $\Omega \in \mathbb{R}^d \ (d \leq 3)$. The system of nonlinear diffusion equations is given by

\begin{align*}
    u_t &= \nabla \cdot (B(u) \nabla \omega), \\
    \omega &= -\gamma \Delta u + D\Psi(u), \\
    \frac{\partial u}{\partial \nu} &= B(u) \frac{\partial \omega}{\partial \nu} = 0, \quad \text{on } \partial \Omega, \\
    u(x, 0) &= u_0(x).
\end{align*}

Here $x = (x_1, \cdots, x_d), \ u, \omega \in (L^2(\Omega))^N, \ \{D\Psi(u)\}_t = \frac{\partial \Psi(u)}{\partial u_t}, \ \partial \Omega$ is the boundary of $\Omega$ and $\nu$ is the normal vector to $\partial \Omega$. $B(u)$ is the $N \times N$ symmetric positive
semi-definite mobility matrix and has the form
\[
\{B(u)\}_{np} \equiv B_{np}(u) := b_n(u_n) \left( \delta_{np} - \left( \sum_{q=1}^{N} b_q(u_q) \right)^{-1} b_p(u_p) \right) \tag{2.2}
\]
where \(\delta_{np}\) is the Kronecker delta.

For \(\eta = (\eta_1, \ldots, \eta_N), \xi = (\xi_1, \ldots, \xi_N) \in (L^2(\Omega))^N\) and \(S = (s_1, \ldots, s_N)^T, P = (p_1, \ldots, p_N)^T\) with \(s_l, p_l \in (L^2(\Omega))^d, \ l = 1, \ldots, N\), we set
\[
\{\eta\}_l = \eta_l, \quad \{\nabla \eta\}_l = \nabla \eta_l, \quad \{\Delta \eta\}_l = \Delta \eta_l, \quad \eta \cdot \xi = \sum_{l=1}^{N} \eta_l \xi_l,
\]
\(\nu \cdot S = (\nu \cdot s_1, \ldots, \nu \cdot s_N)^T, \quad \nabla \cdot S = (\nabla \cdot s_1, \ldots, \nabla \cdot s_N)^T, \quad S \cdot P = \sum_{l=1}^{N} s_l \cdot p_l\).

The concentration of the \(l^{th}\) component of the alloy is denoted by \(u_l\) and so the constraints
\[
(a) \quad 0 \leq u_l \leq 1, \quad (b) \quad \sum_{l=1}^{N} u_l = 1 \tag{2.3}
\]
are satisfied.

The chemical potential \(\omega\) can be defined as the variational derivative of the Ginzburg-Landau free energy
\[
\mathcal{E}(u) := \int_{\Omega} \left( \frac{\gamma}{2} |\nabla u|^2 + \Psi(u) \right) dx, \tag{2.4}
\]
i.e. \(\omega_l = \frac{\delta \mathcal{E}}{\delta u_l}\). The gradient energy coefficient \(\gamma > 0\) and
\[
\Psi(u) := \Psi_1(u) - \frac{1}{2} u^T A u \tag{2.5}
\]
is the homogeneous free energy density. Here, \(A\) is a constant \(N \times N\) symmetric matrix taking into account the interaction between different components. The term \(\Psi_1(u)\) represents the entropy of the system and is usually taken to be of the form
\[
\Psi_1(u) := \theta \sum_{l=1}^{N} u_l \ln u_l, \tag{2.6}
\]
with the absolute temperature \(\theta > 0\). In the deep quench limit \(\theta \to 0\), we take
\[
\Psi_1(u) := \begin{cases} 0 & \text{when } u \text{ satisfies the constraints (2.3),} \\ \infty & \text{otherwise.} \end{cases} \tag{2.7}
\]
From the boundary conditions (2.1c) we have
\[
\frac{d}{dt} \int_{\Omega} u \, dx = 0, \quad \frac{d}{dt} \mathcal{E}(u) \leq 0. \quad (2.8)
\]
Hence, the total mass of each component is conserved and the free energy \( \mathcal{E} \) decays for the system.

**Remark 2.1.** The scalar Cahn-Hilliard equation (1.1) is a special case of the Cahn-Hilliard system (2.1).

In the case \( N = 2 \), assuming that \( A_{11} = A_{22}, B_{11} = B_{22} \), defining \( u := u_2 - u_1 \), \( \omega := \omega_2 - \omega_1 \), \( b(u) = B_{22} - B_{12} \) and \( \theta_c = A_{22} - A_{12} \), we obtain that \((u, \omega)\) satisfies the equation
\[
\begin{align*}
    u_t - \nabla \cdot (b(u) \nabla \omega) &= 0, \quad \omega = -\gamma \Delta u + \Psi'(u), \quad (2.9)
\end{align*}
\]
i.e.
\[
\begin{align*}
    u_t - \nabla \cdot (b(u) \nabla (-\gamma \Delta u + \Psi'(u))) &= 0, \quad (2.10)
\end{align*}
\]
with the homogeneous free energy
\[
\Psi(u) = \frac{\theta}{2} \left( (1 + u) \ln \left( \frac{1 + u}{2} \right) + (1 - u) \ln \left( \frac{1 - u}{2} \right) \right) + \frac{\theta_c}{2} (1 - u^2). \quad (2.11)
\]
This is the Cahn-Hilliard equation with a logarithmic free energy which satisfies the constraint \(|u| \leq 1\).

We can also define \( u := u_2 \) and \( w := \frac{\omega_2 - \omega_1}{2} \), then we obtain the same equation (2.10) with another homogeneous free energy
\[
\Psi(u) = \frac{\theta}{2} (u \ln u + (1 - u) \ln(1 - u)) + \frac{\theta_c}{2} u(1 - u), \quad (2.12)
\]
which satisfies the constraint \( 0 \leq u \leq 1 \).

The Ginzburg-Landau free energy of the equation (2.10)
\[
\mathcal{E}(u) := \int_{\Omega} \left( \frac{\gamma}{2} |\nabla u|^2 + \Psi(u) \right) \, dx \quad (2.13)
\]
also satisfies
\[
\frac{d}{dt} \mathcal{E}(u) \leq 0. \quad (2.14)
\]
2.2 The LDG method for the Cahn-Hilliard system

In this section, we consider the local discontinuous Galerkin method for the Cahn-Hilliard system (2.1) with $N$ components in $\Omega \in \mathbb{R}^d$ with $d \leq 3$. Although we do not address the numerical results in three dimensions in this paper, the LDG methods and the energy stability results of this paper are valid for all $d \leq 3$.

2.2.1 Notation

Let $T_h$ denote a tessellation of $\Omega$ with shape-regular elements $K$. Let $\Gamma$ denote the union of the boundary faces of elements $K \in T_h$, i.e. $\Gamma = \bigcup_{K \in T_h} \partial K$, and $\Gamma_0 = \Gamma \setminus \partial \Omega$.

In order to describe the flux functions we need to introduce some notations. Let $e$ be a face shared by the “left” and “right” elements $K_L$ and $K_R$. For our purpose “left” and “right” can be uniquely defined for each face according to any fixed rule, see, e.g. [36] for more details of such a definition. Define the normal vectors $\mathbf{v}_L$ and $\mathbf{v}_R$ on $e$ pointing exterior to $K_L$ and $K_R$, respectively. If $\psi$ is a function on $K_L$ and $K_R$, but possibly discontinuous across $e$, let $\psi_L$ denote $(\psi|_{K_L})_e$ and $\psi_R$ denote $(\psi|_{K_R})_e$, the left and right trace, respectively.

Let $\mathcal{P}^p(K)$ be the space of polynomials of degree at most $p \geq 0$ on $K \in T_h$. The finite element spaces are denoted by

$$V_h^N = \left\{ \varphi : \varphi|_K \in (\mathcal{P}^p(K))^N, \forall K \in T_h \right\},$$

$$\Sigma_h^N = \left\{ \Phi = (\phi_1, \cdots, \phi_N)^T : \phi_l|_K \in (\mathcal{P}^p(K))^d, l = 1 \cdots N, \forall K \in T_h \right\}.$$  

Note that functions in $V_h^N$ and $\Sigma_h^N$ are allowed to be completely discontinuous across element interfaces.

2.2.2 The LDG methods

To define the local discontinuous Galerkin method, we rewrite (2.1) as a first order system:

$$u_t = \nabla \cdot S,$$  

$$S = B(u)P,$$  

$$P = \nabla(-q + r),$$  

(2.15a)  

(2.15b)  

(2.15c)
\[ q = \gamma \nabla \cdot W, \quad (2.15d) \]
\[ W = \nabla u, \quad (2.15e) \]
\[ r = D\Psi(u), \quad (2.15f) \]

where we use the notations which are defined in Section 2.1.

To simplify the notation, we still use \( u, S, P, q, W \) and \( r \) to denote the numerical solution. The local discontinuous Galerkin method to solve the system (2.15) is as follows: Find \( u, q, r \in V_h^N \) and \( S, P, W \in \Sigma_h^N \), such that, for all test functions \( \rho, \varphi, \xi \in V_h^N \) and \( \Theta, \Phi, \Upsilon \in \Sigma_h^N \),

\[
\begin{align*}
\int_K u_t \cdot \rho dK &= - \int_K S \cdot \nabla \rho dK + \int_{\partial K} \nu \cdot \hat{S} \cdot \rho ds, \\
\int_K S \cdot \Theta dK &= \int_K (B(u)P) \cdot \Theta dK, \\
\int_K P \cdot \Phi dK &= - \int_K (r - q) \cdot (\nabla \cdot \Phi) dK + \int_{\partial K} (\hat{r} - \hat{q}) \cdot (\nu \cdot \Phi) ds, \\
\int_K q \cdot \varphi dK &= - \gamma \int_K W \cdot \nabla \varphi dK + \gamma \int_{\partial K} \hat{W} \cdot \varphi ds, \\
\int_K W \cdot \Upsilon dK &= - \int_K u \cdot (\nabla \cdot \Upsilon) dK + \int_{\partial K} \hat{u} \cdot (\nu \cdot \Upsilon) ds, \\
\int_K r \cdot \xi dK &= \int_K (D\Psi(u)) \cdot \xi dK.
\end{align*}
\] (2.16a)-(2.16f)

The “hat” terms in (2.16a)-(2.16f) in the cell boundary terms from integration by parts are the so-called “numerical fluxes”, which are functions defined on the edges and should be designed based on different guiding principles for different PDEs to ensure stability.

It turns out that we can take the simple choices such that

\[
\begin{align*}
\hat{S}|_e &= S_L, \quad \hat{q}|_e = q_R, \quad \hat{r}|_e = r_R, \quad \hat{W}|_e = W_L, \quad \hat{u}|_e = u_R.
\end{align*}
\] (2.17)

We remark that the choice for the fluxes (2.17) is not unique. In fact the crucial part is taking \( \hat{S} \) and \( \hat{q} \), \( \hat{r} \) from opposite sides and \( \hat{W} \) and \( \hat{u} \) from opposite sides.

**Remark 2.2.** For the scalar Cahn-Hilliard equation

\[ u_t = \nabla \cdot \left( b(u)\nabla(-\gamma \Delta u + \Psi'(u)) \right), \] (2.18)
The LDG scheme becomes: Find \( u, q, r \in V_h^1 \) and \( \mathbf{s}, \mathbf{p}, \mathbf{w} \in \Sigma_h^1 \), such that, for all test functions \( \rho, \varphi, \xi \in V_h^1 \) and \( \eta, \phi, \psi \in \Sigma_h^1 \)

\[
\int_K u_t \rho dK = - \int_K \mathbf{s} \cdot \nabla \rho dK + \int_{\partial K} \mathbf{\nu} \cdot \mathbf{s} \rho ds, \tag{2.19a}
\]

\[
\int_K \mathbf{s} \cdot \eta dK = \int_K b(u) \mathbf{p} \cdot \eta dK, \tag{2.19b}
\]

\[
\int_K \mathbf{p} \cdot \phi dK = - \int_K (r - q) \nabla \cdot \phi dK + \int_{\partial K} \mathbf{\hat{r}} - \mathbf{\hat{q}} \mathbf{\nu} \cdot \phi ds, \tag{2.19c}
\]

\[
\int_K q \varphi dK = - \gamma \int_K \mathbf{w} \cdot \nabla \varphi dK + \gamma \int_{\partial K} \mathbf{\hat{w}} \cdot \mathbf{\varphi} ds, \tag{2.19d}
\]

\[
\int_K \mathbf{w} \cdot \psi dK = - \int_K \mathbf{u} \nabla \cdot \psi dK + \int_{\partial K} \mathbf{\hat{u}} \mathbf{\nu} \cdot \psi ds, \tag{2.19e}
\]

\[
\int_K r \xi dK = \int_K \Psi'(u) \xi dK. \tag{2.19f}
\]

The numerical fluxes are

\[
\mathbf{\hat{s}}|_e = \mathbf{s}_L, \quad \mathbf{\hat{q}}|_e = \mathbf{q}_R, \quad \mathbf{\hat{r}}|_e = r_R, \quad \mathbf{\hat{w}}|_e = \mathbf{w}_L, \quad \mathbf{\hat{u}}|_e = u_R. \tag{2.20}
\]

### 2.2.3 Energy stability

We will prove the theoretical results of the energy stability for the general nonlinear system case with the choice of the fluxes in the previous section.

**Proposition 2.1.** (Energy stability) The solution to the schemes (2.16) and (2.17) with the boundary conditions (2.1c) satisfies the energy stability

\[
\frac{d}{dt} \int_{\Omega} \left( \gamma \frac{2}{2} \mathbf{W} \cdot \mathbf{W} + \Psi(u) \right) dx \leq 0.
\]

**Proof.** Choosing the test function \( \xi = -u_t \in V_h^1 \) in (2.16f), we obtain

\[
- \int_K r \cdot u_t dK = - \int_K (D\Psi(u)) \cdot u_t dK. \tag{2.21}
\]

For the equation (2.16e), we first take the time derivative, then choose the test function \( \Upsilon = \gamma \mathbf{W} \in \Sigma_h^1 \). We obtain

\[
\gamma \int_K \mathbf{W}_t \cdot \mathbf{W}_dK = - \gamma \int_K u_t \cdot (\nabla \cdot \mathbf{W}) dK + \gamma \int_{\partial K} \mathbf{\hat{u}}_t \cdot (\mathbf{\nu} \cdot \mathbf{W}) ds. \tag{2.22}
\]

For (2.16a), (2.16b), (2.16c) and (2.16d), we take the test functions

\[
\rho = r - q, \quad \Theta = -P, \quad \Phi = S, \quad \varphi = u_t.
\]
Then we have
\[
\int_K u_t \cdot (r - q) dK = - \int_K S \cdot (\nabla (r - q)) dK + \int_{\partial K} \nu \cdot \tilde{S} \cdot (r - q) ds, \tag{2.23}
\]
\[
- \int_K S \cdot P dK = - \int_K (B(u)P) \cdot P dK, \tag{2.24}
\]
\[
\int_K P \cdot S dK = - \int_K (r - q) \cdot (\nabla \cdot S) dK + \int_{\partial K} (\tilde{r} - \tilde{q}) \cdot (\nu \cdot S) ds, \tag{2.25}
\]
\[
\int_K q \cdot u_t dK = - \gamma \int_K W \cdot (\nabla u_t) dK + \gamma \int_{\partial K} \hat{\nu} \cdot W \cdot u_t ds. \tag{2.26}
\]

Summing up the equations (2.21)-(2.26), we obtain
\[
\int_K \left( \gamma W \cdot W_t + (D\Psi(u)) \cdot u_t \right) + \int_K (B(u)P) \cdot P dK = 0.
\]

Because \(B(u)\) is semi-positive, we have the energy stability
\[
\frac{d}{dt} \int_\Omega \left( \gamma W \cdot W + \Psi(u) \right) dx \leq 0.
\]

\[\square\]

\textbf{Remark 2.3.} Proposition 2.1 is also true for the LDG scheme (2.19) and (2.20) for the scalar Cahn-Hilliard equation (2.18). The proof goes along the same line and is simpler. We thus omit the details.
3 Numerical results

In this section we perform numerical experiments of the local discontinuous Galerkin method applied to the Cahn-Hilliard equation and system. Time discretization is by the third order TVD Runge-Kutta method [29]. We have chosen $\Delta t$ suitably small so that spatial errors dominate in the numerical results. This is not the most efficient method for the time discretization to our LDG scheme. However, we will not address the issue of time discretization efficiency in this paper. All the computations were performed in double precision. We have verified with the aid of successive mesh refinements, that in all cases, the results shown are numerically convergent.

3.1 Numerical results for the Cahn-Hilliard equation

3.1.1 One space dimension

In this section, we give the numerical test results for the one-dimensional Cahn-Hilliard equation.

Example 3.1.

We consider

$$u_t = -\left(b(u)\left(\gamma u_{xxx} - (\Psi'(u))_x\right)\right)_x \quad (3.1)$$

with $\Psi(u) = \frac{1}{2}(1 - u^2)$, $b(u) = 1 - u^2$ and $\gamma = 0.01$ in $\Omega = (0, 1)$. The initial condition is

$$u_0(x) = \begin{cases} 
\cos\left(\frac{x - \frac{1}{2}}{\sqrt{\gamma}}\right) - 1, & \text{if } |x - \frac{1}{2}| \leq \frac{\pi\sqrt{\gamma}}{2}, \\
-1, & \text{otherwise}. 
\end{cases} \quad (3.2)$$

The boundary conditions are taken as

$$u_x = b(u)u_{xxx} = 0 \quad (3.3)$$

at both ends. We note that $u_0(x)$ is in $H^1(\Omega)$ and not in $H^2(\Omega)$. Elliot and Garcke [18] proved existence of a solution with the property that $u \in L^2(0,T;H^2(\Omega))$ for
Table 3.1: Accuracy test for the Cahn-Hilliard equation (3.1) with the stationary solution (3.4). Uniform meshes with $J$ cells at time $t = 0.1$.

arbitrary initial data $u_0 \in H^1(\Omega)$. Our numerical tests verify their conclusion that the numerical solution appears to spread to the stationary $C^1([0, 1])$ solution:

$$u_{\text{steady}}(x) = \begin{cases} \frac{1}{\pi} \left[ 1 + \cos \left( \frac{x - \frac{1}{2}}{\sqrt{\gamma}} \right) \right] - 1, & \text{if } |x - \frac{1}{2}| \leq \pi \sqrt{\gamma}, \\ -1, & \text{otherwise.} \end{cases} \quad (3.4)$$

The $L^2$ and $L^\infty$ errors and the numerical orders of accuracy for the stationary solution $u_{\text{steady}}$ at time $t = 0.1$ with uniform meshes in $[0, 1]$ are contained in Table 3.1. In Fig. 3.1, we show the numerical results at $t = 0.1$ using $P^1$ elements on the uniform mesh with 80 cells. With fewer cells, our scheme gets the same results comparing the numerical calculations performed by Barrett et al. [3].

Example 3.2.

We consider the Cahn-Hilliard equation (3.1) with $b(u) = 1$ or $b(u) = 1 - u^2$ and $\gamma = 10^{-3}$ in $\Omega = (0, 1)$. We take the free energy

$$\Psi(u) = \frac{\theta}{2} \left[ (1 + u) \ln \left( \frac{1 + u}{2} \right) + (1 - u) \ln \left( \frac{1 - u}{2} \right) \right] + \frac{1}{2} (1 - u^2) \quad (3.5)$$
Figure 3.1: The numerical solution of the equation (3.1) with the initial condition (3.2) and the boundary conditions (3.3) at $t = 0.1$ using $P^1$ elements on the uniform mesh with 80 cells.

with $\theta = 0$ (the deep quench limit) or 0.3. The initial condition is

$$u_0(x) = \begin{cases} 
1, & \text{if } 0 \leq x \leq \frac{1}{3} - \frac{1}{20}, \\
20(\frac{1}{3} - x), & \text{if } |x - \frac{1}{3}| \leq \frac{1}{20}, \\
-20|x - \frac{41}{50}|, & \text{if } |x - \frac{41}{50}| \leq \frac{1}{20}, \\
-1, & \text{otherwise}.
\end{cases} \tag{3.6}$$

The boundary conditions are (3.3).

We use $P^1$ element and a uniform mesh with 80 cells. The results include both $\theta = 0$ (the deep quench limit) and $\theta = 0.3$ for constant and degenerate mobility $b(u) = 1$ or $b(u) = 1 - u^2$. The simulations are stopped when the obtained profiles do not change for a long time. The numerical results compare very well with numerical calculations performed by Barrett et al. [3]. From the numerical results in Fig. 3.2, we have the following observation:

- For the constant mobility $b(u) = 1$, the “bump” is swept away quickly. This is due to the fact that mobility is positive in the pure phases.

- For the degenerate mobility $b(u) = 1 - u^2$ with logarithmic free energy (3.5),
Figure 3.2: The solution of the equation (3.1) with the initial condition (3.6) and the boundary conditions (3.3) at different time $T$ with $P^1$ element on the uniform mesh with 80 cells.

the time scale of the diffusion is greatly increased.

- For the degenerate mobility $b(u) = 1 - u^2$ and the quench limit free energy, the “bump” does not lose mass. As $\theta$ goes to zero, the minima of the free energy $\Psi(u)$ in (3.5) converge to $u = \pm 1$ (see Fig. 3.3). This implies that the diffusion through the bulk becomes smaller for lower temperature.

3.1.2 Two space dimensions

In this section, we present the numerical results for the two-dimensional Cahn-Hilliard equation.
Figure 3.3: The free energy $\Psi(u)$ in (3.5) with $\theta = 0.3, 0.5, 0.6$.

**Example 3.3.**

We consider the Cahn-Hilliard equation

$$u_t = \nabla \cdot \left( b(u)\nabla (-\gamma \Delta u + \Psi'(u)) \right) \quad (3.7)$$

with

$$\Psi(u) = 600(u \ln u + (1 - u) \ln(1 - u)) + 1800(1 - u), \quad b(u) = 1, \quad \gamma = 1.$$  

The initial condition is

$$u_0(x) = \begin{cases} 
0.71 & x \in \Omega_1, \\
0.69 & x \in \Omega_2,
\end{cases} \quad (3.8)$$

where the square domain

$$\Omega = (-0.5, 0.5) \times (-0.5, 0.5), \quad \Omega_1 = (-0.2, 0.2) \times (-0.2, 0.2), \quad \Omega_2 = \Omega - \Omega_1.$$  

The boundary conditions are

$$\frac{\partial u}{\partial \nu} = b(u)\nabla \omega \cdot \nu = 0, \quad \text{on } \partial \Omega. \quad (3.9)$$

We use the $P^0$ and $P^1$ element on the uniform meshes with 40 x 40 and 80 x 80 cells respectively. The contours at $t = 8 \times 10^{-5}$ are shown in Fig. 3.4. We can see
Figure 3.4: The contours of $u(x,t)$ for the equation (3.7) with the initial condition (3.8) and the boundary conditions (3.9) when $t = 8 \times 10^{-5}$. $P^0$ and $P^1$ elements on the uniform mesh with $40 \times 40$ and $80 \times 80$ cells.

that the solution structure is well resolved even for the coarser mesh. The numerical results compare very well with the numerical calculations performed by Wells et al. [31].

**Example 3.4.**

In the square domain $\Omega = (-0.5, 0.5) \times (-0.5, 0.5)$, we consider the Cahn-Hilliard equation (3.7) with

$$\Psi(u) = 3000(u \ln u + (1 - u) \ln(1 - u)) + 9000u(1 - u), \quad b(u) = u(1 - u), \quad \gamma = 1.$$
Figure 3.5: The contours evolution of $u(x, t)$ for the equation (3.7) at different time from a randomly perturbed initial condition with $P^1$ element on the uniform mesh with $80 \times 80$ cells.

The initial condition $u_0$ is a random perturbation of uniform state $u = 0.63$ with a fluctuation no larger than 0.05. The boundary conditions are taken as (3.9). This example is used in Sec. 5.3 in [31] (the initial condition is identical in the statistical sense). We use the $P^1$ element on a uniform mesh with $80 \times 80$ cells. The concentration evolution can be categorized in two stages. The first stage is governed by spinodal decomposition and phase separation (the first four figures in Fig. 3.5). The second stage is governed by grain coarsening (from $t = 8 \times 10^{-6}$ onwards). Fig. 3.5 shows statistically similar patterns in the numerical solution as those in Wells et al. [31].
3.2 Numerical results for the Cahn-Hilliard system

3.2.1 One space dimension

In this section, we present the numerical experiment results for the one-dimensional Cahn-Hilliard system.

Example 3.5.

We consider a ternary system in \( \Omega = (0, 1) \) by Blowey et al. [7]

\[
    u_t + \gamma u_{xxxx} + \theta_c u_{xx} - B \{ D\Psi_1(u) \}_{xx} = 0, \tag{3.10}
\]

with

\[
    B = \begin{pmatrix}
        \frac{2}{3} & -\frac{1}{3} & -\frac{1}{3} \\
        -\frac{1}{3} & \frac{2}{3} & -\frac{1}{3} \\
        -\frac{1}{3} & -\frac{1}{3} & \frac{2}{3}
    \end{pmatrix}
\]

and

\[
    \Psi(u) = \theta(u_1 \ln u_1 + u_2 \ln u_2 + u_3 \ln u_3) + \theta_c(u_1 u_2 + u_2 u_3 + u_3 u_1).
\]

The boundary conditions are

\[
    u_x = Bu_{xxx} = 0 \tag{3.11}
\]

at both ends.

We first perform a linear stability analysis. We seek a solution of the form

\[
    u_i(x, t) = m_i + \sum_{n=1}^{\infty} c^n_i(t) \cos n\pi x, \quad i = 1, \cdots, 3,
\]

where \( \mathbf{m} = (m_1, m_2, m_3) \) is the mean concentration and \( |c^n_i(t)| \ll 1 \). Note that \( m_1 + m_2 + m_3 = 1 \) and \( c_1^n(t) + c_2^n(t) + c_3^n(t) = 0 \). Linearizing \( D\Psi_1(u) \) about \( m_i \) and substituting into (3.10), we obtain the ordinary differential equations

\[
    \frac{dc^n_i}{dt} + n^4 \pi^4 \gamma c^n_i + n^2 \pi^2 H c^n_i = 0, \tag{3.12}
\]

where

\[
    c^n_i(t) = (c_1^n(t), c_2^n(t)), \quad H = \begin{pmatrix}
        \frac{2\theta}{3} \left( \frac{1}{m_1} + \frac{1}{2(1-m_1-m_2)} \right) - \theta_c & -\frac{2\theta}{3} \left( \frac{1}{2m_2} - \frac{1}{2(1-m_1-m_2)} \right) \\
        -\frac{2\theta}{3} \left( \frac{1}{2m_1} - \frac{1}{2(1-m_1-m_2)} \right) & \frac{2\theta}{3} \left( \frac{1}{m_2} + \frac{1}{2(1-m_1-m_2)} \right) - \theta_c
    \end{pmatrix}.
\]
The solution of (3.12) is given by

\[ c^n(t) = e^{-n^2 \pi^2 \gamma t} \times e^{-n^2 \pi^2 H t} c^n(0). \]

For the growth of one or more of the components \( u_1, u_2 \), a necessary condition is that the eigenvalues of \( H \) is smaller than \(-\gamma \pi^2\). When \( m_2 = m_1 \), we have

\[ \det H = \frac{(\theta/\theta_c + 6m_1^2 - 3m_1)(\theta/\theta_c - m_1)}{3m_1^2(1 - 2m_1)} \theta_c. \]

We see from Fig. 3.6 that two curves \( \theta/\theta_c = m_1 \) and \( \theta/\theta_c = 3m_1 - 6m_1^2 \) define the four regions where \( H \) is positive, negative definite or indefinite.

![Figure 3.6: The positive, negative definite and indefinite regions of \( H \), when \( m_2 = m_1 \).](image)

We take \( \theta = 0.2, \theta_c = 1 \) and \( \gamma = 5.0 \times 10^{-3} \). The initial conditions are random perturbations of the uniform state \( m \) with the fluctuation no larger than 0.01. We use \( P^1 \) element and a uniform mesh with 80 cells. The simulations are stopped when the obtained profiles do not change for a long time.

We perform four experiments with initial data inside the positive, negative definite and indefinite regions respectively, by taking \( m_1 = 1/20, 3/20, 1/3, 19/20 \) (points a, b, c and d in Fig. 3.6 respectively)

- \( m_1 = 1/20 \) in the positive definite region.

Fig. 3.7 shows the time evolution of the ternary system (3.10). As expected, the homogeneous system is stable and no phase separation happens.
Figure 3.7: The evolution of system (3.10) at different time $T$ with $m_1 = 1/20$ when $\theta = 0.2$ and $\theta_c = 1$.

- $m_1 = 3/20$ in the indefinite region.

Fig. 3.8 shows the time evolution of the ternary system (3.10). Initially the third phase $u_3$ dominates. For some time the evolution is in the direction of $u_1 = u_2$ with two-phase structure.

- $m_1 = 1/3$ in the negative definite region.

Fig. 3.9 shows the time evolution of the ternary system (3.10). We observe three phases in the early stages of the spinodal decomposition.

- $m_1 = 19/20$ in the indefinite region.

Fig. 3.10 shows the time evolution of the ternary system (3.10). The decomposition process is like a binary alloy. After the quench, only $u_1$ and $u_2$ are separated and there is no spatial area where $u_3$ is dominant.

### 3.2.2 Two space dimensions

In this section, we present the numerical simulation results for the two-dimensional Cahn-Hilliard system.

**Example 3.6.**
Figure 3.8: The evolution of system (3.10) at different time $T$ with $m_1 = 3/20$ when $	heta = 0.2$ and $\theta_c = 1$.

We consider a ternary system in $\Omega = (0,1) \times (0,1)$

\[ \mathbf{u}_t = \nabla \cdot (\mathbf{B}(\mathbf{u}) \nabla \omega), \quad (3.13) \]

\[ \omega = -\gamma \Delta \mathbf{u} + D \Psi_1(\mathbf{u}) - \mathbf{A} \mathbf{u} \]

where $\Psi_1(\mathbf{u})$ is given by (2.6) and

\[
\mathbf{B}(\mathbf{u}) = \begin{pmatrix}
    u_1(u_2 + u_3) & -u_1 u_2 & -u_1 u_3 \\
    -u_1 u_2 & u_2(u_1 + u_3) & -u_2 u_3 \\
    -u_1 u_3 & -u_2 u_3 & u_3(u_1 + u_2)
\end{pmatrix},
\quad
\mathbf{A} = -\theta_c \begin{pmatrix}
    0 & 1 & 1 \\
    1 & 0 & 1 \\
    1 & 1 & 0
\end{pmatrix}.
\]
Figure 3.9: The evolution of system (3.10) at different time $T$ with $m_1 = 1/3$ when
$\theta = 0.2$ and $\theta_c = 1$.

We take $\theta = 1200$, $\theta_c = 3600$ and $\gamma = 1$. The initial data is

$$
u_0(x_1, x_2) = \begin{cases} 
(0, 0, 1)^T & \text{if } 0 \leq x_1 \leq \frac{13}{16} \text{ and } x_2 > 0.65 + \frac{\sqrt{3}}{8\pi} \cos(8\pi x_1) \\
& \text{or } \frac{13}{16} \leq x_1 \leq \frac{13}{16} + \frac{0.15}{\sqrt{3}} \text{ and } x_2 > 0.65 - \sqrt{3}(x_1 - \frac{13}{16}) \\
& \text{or } \frac{13}{16} + \frac{0.15}{\sqrt{3}} \leq x_1 \text{ and } x_2 > \frac{1}{2}, \\
(0, 1, 0)^T & \text{if } 0 \leq x_1 \leq \frac{13}{16} \text{ and } x_2 < 0.35 - \frac{\sqrt{3}}{8\pi} \cos(8\pi x_1) \\
& \text{or } \frac{13}{16} \leq x_1 \leq \frac{13}{16} + \frac{0.15}{\sqrt{3}} \text{ and } x_2 < 0.35 + \sqrt{3}(x_1 - \frac{13}{16}) \\
& \text{or } \frac{13}{16} + \frac{0.15}{\sqrt{3}} \leq x_1 \text{ and } x_2 < \frac{1}{2}, \\
(0, \frac{1}{2}, \frac{1}{2})^T & \text{if } \frac{13}{16} + \frac{0.15}{\sqrt{3}} \leq x_1 \text{ and } x_2 = \frac{1}{2}, \\
(1, 0, 0)^T & \text{otherwise.}
\end{cases}$$

(3.14)
The boundary conditions are
\[
\frac{\partial u}{\partial \nu} = B(u) \frac{\partial \omega}{\partial \nu} = 0, \quad \text{on } \partial \Omega. \tag{3.15}
\]
We show the contours of \( u_1(x,t) \), \( u_2(x,t) \) and \( u_3(x,t) \) at \( t = 8 \times 10^{-5} \) in Fig. 3.11 using \( P^1 \) element on a uniform mesh with 80 \( \times \) 80 cells. As expected, the symmetry of the initial data is maintained during the evolution. We find that the interface of the two components is “wetted” by the third component. This is understood as the energy required to go directly from the first to the third component is much greater than that required to go via the intermediate second component. This phenomenon is known as “wetting”. 

Figure 3.10: The evolution of system (3.10) at different time \( T \) with \( m_1 = 19/20 \) when \( \theta = 0.2 \) and \( \theta_c = 1 \).
Figure 3.11: The contours of $u_1(x, t)$, $u_2(x, t)$ and $u_3(x, t)$ for the equation (3.13) with the initial condition (3.14) and the boundary conditions (3.15) when $t = 8 \times 10^{-5}$. $P^1$ elements on the uniform mesh with $80 \times 80$ cells.
4 Conclusion

We have developed local discontinuous Galerkin methods to solve the Cahn-Hilliard equation and the Cahn-Hilliard system. The energy stability is proven for general nonlinear case. Numerical examples for one-dimensional and two dimensional cases are given to illustrate the accuracy and capability of the methods. Although not addressed in this paper, the LDG methods are flexible for general geometry, unstructured meshes and $h$-$p$ adaptivity, and have excellent parallel efficiency. The LDG method has a good potential in solving the Cahn-Hilliard equations and similar nonlinear equations in mathematical physics.
