Abstract

The main purpose of this paper is to analyze the stability and error estimates of the local discontinuous Galerkin (LDG) methods coupled with implicit-explicit (IMEX) time discretization schemes, for solving one-dimensional convection-diffusion equations with a nonlinear convection. Both Runge-Kutta and multi-step IMEX methods are considered. By the aid of the energy method, we show that the IMEX LDG schemes are unconditionally stable for the nonlinear problems, in the sense that the time-step $\tau$ is only required to be upper-bounded by a positive constant which depends on the flow velocity and the diffusion coefficient, but is independent of the mesh size $h$. We also give optimal error estimates for the IMEX LDG schemes, under the same temporal condition, if a monotone numerical flux is adopted for the convection. Numerical experiments are given to verify our main results.

Keywords: local discontinuous Galerkin method, implicit-explicit scheme, convection-diffusion equation, stability analysis, error estimate, energy method

1. Introduction

In this paper we extend our previous work \cite{14} and continue to analyze the stability and error estimates of some fully discrete local discontinuous Galerkin (LDG) schemes coupled with implicit-explicit (IMEX) time discretization, for solving a semilinear convection-diffusion problem with periodic boundary condition in one dimension.

Preprint submitted to Journal of AMC September 16, 2014
The LDG method was introduced by Cockburn and Shu for convection-diffusion problems in [8], motivated by the work of Bassi and Rebay [2] for compressible Navier-Stokes equations. As an extension of discontinuous Galerkin (DG) schemes for hyperbolic conservation laws [9], this scheme shares the advantages of the DG methods, such as good stability, high order accuracy, and flexibility on $h$-$p$ adaptivity and on complex geometry. Besides, a key advantage of this scheme is the local solvability, that is, the auxiliary variables approximating the gradient of the solution can be locally eliminated. Over the past twenty years, there has been extensive study of the LDG methods for steady problems or in the semi-discrete framework, such as for elliptic problems [4], convection-diffusion problems [3], the Stokes system [7], the KdV type equations [18], Hamilton-Jacobi equations [17], time-dependent fourth order problems [10], and so on.

The time-discretization to the LDG method is necessary and should be studied carefully, in order to keep the above advantages and the original efficiency. In the fully-discrete framework, explicit Runge-Kutta time discretization methods were analyzed in [15]. This kind of time discretization is stable, efficient and accurate for solving convection-dominated convection-diffusion problems. However, for convection-diffusion equations which are not convection-dominated, explicit time discretization will suffer from a stringent time step restriction for stability [16]. When it comes to such problems, a natural consideration to overcome the small time step restriction is to use implicit time marching. Furthermore, in many applications the convection terms are often nonlinear, hence it would be desirable to treat them explicitly while using implicit time discretization only for the linear diffusion terms. Such time discretizations are called implicit-explicit (IMEX) time discretizations [1]. Even for nonlinear diffusion terms, IMEX time discretizations would show their advantages in obtaining an elliptic algebraic system, which is easy to solve by many iterative methods.

If both convection and diffusion are treated implicitly, the resulting algebraic system will be far from elliptic and convergence of many iterative solvers will suffer.

In [14] we have discussed the LDG scheme coupled with three specific Runge-Kutta type IMEX schemes given in [1] and [3], for solving linear convection-diffusion problems. We have shown that those schemes are unconditionally stable in the sense that the time step $\tau$ is only required to be upper bounded by a fixed constant which depends solely on the coefficients of convection and diffusion, but is independent of the mesh size. In this paper we will extend the above work to the nonlinear convection case, which is widely used in practice. Also, we will apply our analysis technique to some multi-step IMEX schemes given in [11]. Furthermore, we would like to show the optimal error estimates for the convection-diffusion problem with a nonlinear convection, under the similar temporal condition as in the stability analysis, if a general monotone numerical flux is adopted.

We will mainly perform the error estimates of the LDG spatial discretization coupled with the third order IMEX RK time marching method given in [3] for solving the nonlinear problems. As we pointed out in [14], there is one more stage
for the explicit part than the implicit part in the third order IMEX RK scheme in [3], which makes the error analysis more complicated than the linear case [14], where we only considered the upwind numerical flux for the convection part, so that we can find a proper projection (Gauss-Radau projection) to eliminate the cell interface errors to obtain optimal error accuracy. While for the nonlinear problems, if we consider a general monotone numerical flux, it is difficult to find such projection to eliminate the cell interface errors, so we would like to resort to the technique used in [20] and [21] to carry out the error analysis for the third order IMEX LDG scheme. In the analysis, a prior assumption is required, and the idea in [12] to divide the total error into spatial error and temporal error is also adopted. The error estimates for the first and second order IMEX LDG schemes presented in [14] will not be presented in this paper, because there are the same number of explicit stages and implicit stages for these two lower order schemes, the analysis is simpler than the third order scheme; see Remark 3.

The paper is organized as follows. In Section 2, we present the semi-discrete LDG scheme and some elemental conclusions about the finite element space as well as the LDG spatial discretization. In Section 3, we will present three specific IMEX RK fully-discrete LDG schemes for the model problem, and will concentrate on obtaining stability analysis and error estimate for the third order RK type IMEX LDG methods. Also, we present some multi-step IMEX LDG schemes and their stability analysis in Section 4. In Section 5, we give numerical results to verify our results. The concluding remarks and some technical proofs are given in Section 6 and the Appendix, respectively.

2. The LDG method

In this section we present the definition of the semi-discrete LDG schemes for one dimensional nonlinear convection-diffusion problem

\[ U_t + f(U)_x - dU_{xx} = 0, \quad (x, t) \in Q_T = (a, b) \times (0, T], \]

with periodic boundary condition and the initial solution \( U(x, 0) = U_0(x) \), where the diffusion coefficient \( d > 0 \) is a constant, and \( f \) is assumed to be differentiable.

2.1. Discontinuous finite element space

Let \( T_h = \{ I_j = (x_j, x_{j+1}) \} \) be the partition of \( \Omega \), where \( x_1 = a \) and \( x_{N+1} = b \) are two boundary endpoints. Denote the cell length as \( h_j = x_{j+1} - x_j \) for \( j = 1, \ldots, N \), and define \( h = \max_j h_j \). We assume \( T_h \) is quasi-uniform in this paper, that is, there exists a positive constant \( \nu \) such that for all \( j \) there holds \( h_j/h \geq \nu \), as \( h \) goes to zero.

Associated with this mesh, we define the discontinuous finite element space

\[ V_h = \{ v \in L^2(\Omega) : v|_{I_j} \in \mathcal{P}_k(I_j), \forall j = 1, \ldots, N \}, \]

where \( \mathcal{P}_k(I_j) \) denotes the space of polynomials in \( I_j \) of degree at most \( k \geq 1 \). Furthermore, we would like to consider the (mesh-dependent) broken Sobolev space

\[ H^1(T_h) = \{ \phi \in L^2(\Omega) : \phi|_{I_j} \in H^1(I_j), \forall j = 1, \ldots, N \}, \]
which contains the discontinuous finite element space $V_h$. Note that the functions in this space are allowed to have discontinuities across element interfaces. At each element interface point, for any piecewise function $p$, there are two traces along the right-hand and left-hand, denoted by $p^+$ and $p^-$, respectively. As usual, the jump is denoted by $[p] = p^+ - p^-$. 

Now we present the following inverse properties with respect to the finite element space $V_h$, where the standard norms and semi-norms in Sobolev spaces are used. For any function $v \in V_h$, there exists a positive constant $\mu > 0$ independent of $v, h$ and $j$ such that

\[
\|v_x\|_{I_j} \leq \mu h^{-1} \|v\|_{I_j}, \\
\|v\|_{\infty, I_j} \leq \mu h^{-1/2} \|v\|_{I_j}, \\
\|v\|_{\partial I_j} \leq \sqrt{\mu h^{-1}} \|v\|_{I_j},
\]

where $\|v\|_{\partial I_j} = \sqrt{(v^+_{-j+\frac{1}{2}})^2 + (v^-_{-j+\frac{1}{2}})^2}$ is the $L^2$-norm on the boundary of $I_j$. We call $\mu$ the inverse constant and denote $\|v\|_{I_j} = (\sum_{j=1}^N \|v\|_{\partial I_j}^2)^{1/2}$.

In this paper we will use two Gauss-Radau projections, from $H^1(T_h)$ to $V_h$, denoted by $\pi_h^-$ and $\pi_h^+$ respectively. For any function $p \in H^1(T_h)$, the projection $\pi_h^\pm p$ is defined as the unique element in $V_h$ such that, in each element $I_j = (x_{-j+\frac{1}{2}}, x_{-j+\frac{1}{2}})$

\[
(\pi_h^- p - p, v)_{I_j} = 0, \quad \forall v \in P_{k-1}(I_j), \quad (\pi_h^- p)^{\pm}_{-j+\frac{1}{2}} = p^{\pm}_{-j+\frac{1}{2}}; \\
(\pi_h^+ p - p, v)_{I_j} = 0, \quad \forall v \in P_{k-1}(I_j), \quad (\pi_h^+ p)^{\pm}_{-j+\frac{1}{2}} = p^{\pm}_{-j+\frac{1}{2}}.
\]

Denote by $\eta = p - \pi_h^\pm p$ the projection error. By a standard scaling argument \[4\], it is easy to obtain the following approximation property

\[
\|\eta\|_{I_j} + h^{1/2} \|\eta\|_{\infty, I_j} + h^{1/2} \|\eta\|_{\partial I_j} \leq C h^{\min(k+1,s)} \|p\|_{H^s(T_h)}, \quad \forall j,
\]

where the bounding constant $C > 0$ is independent of $h$ and $j$.

In what follows we will mainly use the inverse inequalities \[4\] and the approximation property \[4\] in global form by summing up the above local inequalities over $j = 1, 2, \ldots, N$. The conclusions are almost the same as their local conclusions, so they are omitted here.

2.2. Semi-discrete LDG scheme

Following \[8\], we introduce the auxiliary variable $Q = \sqrt{a} U$, and find the approximation solutions in the discontinuous finite element space, based on the following equivalent first-order differential system

\[
U_t + (f(U) - \sqrt{a} Q)_x = 0, \quad Q + (-\sqrt{a} U)_x = 0, \quad (x, t) \in QT,
\]

with the same initial condition and the periodic boundary condition.
The semi-discrete LDG scheme is defined as follows: for any \( t > 0 \), find the numerical solution \((u(x, t), q(x, t)) \in V_h \times V_h\), such that, for any test functions \( z = (v, r) \in V_h \times V_h\), the variation forms

\[
\begin{align*}
(u_t, v)_j &= \mathcal{H}_j(f(u), v) - \sqrt{d} \mathcal{L}_j^+(q, v), \\
(q, r)_j &= -\sqrt{d} \mathcal{L}_j^-(u, r),
\end{align*}
\] (2.8a)

hold in each cell \( I_j, j = 1, 2, \ldots, N \). Here and below we drop the arguments \( x \) and \( t \) if there is no confusion. Here \((\cdot, \cdot)_j\) is the usual inner product in \( L^2(I_j) \) and

\[
\begin{align*}
\mathcal{H}_j(f(u), v) &= (f(u), v_x)_j - \hat{f}(u)_{j+\frac{1}{2}} v^-_{j+\frac{1}{2}} + \hat{f}(u)_{j-\frac{1}{2}} v^+_{j-\frac{1}{2}}, \\
\mathcal{L}_j^\pm(v, r) &= (v, r_x)_j - v^\pm_{j+\frac{1}{2}} r^-_{j+\frac{1}{2}} + v^\pm_{j-\frac{1}{2}} r^+_{j-\frac{1}{2}},
\end{align*}
\] (2.9a)

where \( \hat{f}(u) = \hat{f}(u^-, u^+) \) is a monotone numerical flux, which is Lipschitz continuous, consistent with \( f(u) \), nondecreasing and nonincreasing with respect to its first and second arguments, respectively. Note that the alternating numerical flux \( \hat{f} \) is adopted in (2.9b).

For the convenience of analysis, we sum up the variational formulations (2.8) over all cells. Then we can write the semi-discrete LDG scheme in the global form: for any \( t > 0 \), find the numerical solution \((u, q) \in V_h \times V_h\) such that the variation equations

\[
\begin{align*}
(u_t, v) &= \mathcal{H}(f(u), v) + \mathcal{L}(q, v); \\
(q, r) &= \mathcal{K}(u, r),
\end{align*}
\] (2.10a)

hold for any \( z = (v, r) \in V_h \times V_h\), where \((\cdot, \cdot) = \sum_{j=1}^{N} (\cdot, \cdot)_j\) is the inner product in \( L^2(\Omega) \), and

\[
\begin{align*}
\mathcal{H} &= \sum_{j=1}^{N} \mathcal{H}_j, & \mathcal{L} &= -\sqrt{d} \sum_{j=1}^{N} \mathcal{L}_j^+, & \mathcal{K} &= -\sqrt{d} \sum_{j=1}^{N} \mathcal{L}_j^-.
\end{align*}
\] (2.11)

The initial condition \( u(x, 0) \) can be taken as any approximation of the given initial solution \( U_0(x) \), for example, the local Gauss-Radau projection (2.5) of \( U_0(x) \). We have now defined the semi-discrete LDG scheme.

2.3. Properties of the LDG spatial discretization

In this subsection, we will give several lemmas to illustrate some properties of the LDG spatial discretization, which will be used many times in this paper.

First we would like to consider the linear part. Lemma 2.1 demonstrates the skew symmetric property of the operators \( \mathcal{L} \) and \( \mathcal{K} \), and Lemma 2.2 results from the definitions of \( \mathcal{L}^\pm \) and the Gauss-Radau projection. The proofs are straightforward, so we skip the details. For the readers who are interested in the proof, we refer to [10]. Lemma 2.3 given in [14] builds up an important relationship between the auxiliary variable and the prime variable, which plays a key role in the stability analysis.
Lemma 2.1. For any \( w, v \in H^1(T_h) \), there holds \( \mathcal{L}(w, v) = -\mathcal{K}(v, w) \).

Lemma 2.2. For any \( w \in H^1(T_h) \) and \( v \in V_h \), there holds \( \mathcal{L}^\pm(\pi_h^\pm w, v) = 0 \).

Lemma 2.3. Suppose \( w = (u, q) \in V_h \times V_h \) satisfy (2.10b), then
\[
\|u_x\| + \sqrt{\mu h^{-1}}|u| \leq \frac{C_{\mu}}{\sqrt{d}}\|q\|, \tag{2.12}
\]
where the bounding constant \( C_{\mu} \) is independent of \( h \) and \( d \).

Next we consider the nonlinear part, namely, \( \mathcal{H} \), and present two conclusions. Lemma 2.4 is about the non-positivity; see [13]. Lemma 2.5 gives two boundedness properties. To derive Lemma 2.5, we would like to assume that the consistent numerical flux \( \hat{f} \) is Lipschitz continuous with respect to each component, and denote the Lipschitz constant as \( C_f \). Then we have
\[
|\hat{f}(p_1^-, p_1^+) - \hat{f}(p_2^-, p_2^+)| \leq C_f(|p_1^- - p_2^-| + |p_1^+ - p_2^+|), \quad \forall p_1, p_2, \tag{2.13a}
\]
which implies
\[
|f'(p)| \leq C_f, \quad \forall p. \tag{2.13b}
\]
if \( f \) is differentiable. This assumption is acceptable, if we focus on the error estimate to smooth solutions.

Remark 1. In this paper, we would like to use the notation \( C_f \) to denote the generic positive constant, which is independent of the mesh size \( h \) and the time step \( \tau \). Each occurrence may have a different value.

Lemma 2.4. For any \( v \in H^1(T_h) \), there holds \( \mathcal{H}(f(v), v) \leq 0 \).

In this paper, we will use the notation \( D(u, w; v) \) to represent the difference between \( \mathcal{H}(f(u), v) \) and \( \mathcal{H}(f(w), v) \) for arbitrary \( u, w \in H^1(T_h) \) and \( v \in V_h \), i.e,
\[
D(u, w; v) = \mathcal{H}(f(u), v) - \mathcal{H}(f(w), v). \tag{2.14}
\]

Lemma 2.5. For any \( u, w, v \in V_h \), there hold the following inequalities
\[
|\mathcal{H}(f(u), v)| \leq C_f \left( \|u_x\| + \sqrt{\mu h^{-1}}|u| \right) \|v\|, \tag{2.15}
\]
\[
|D(u, w; v)| \leq C_f \|u - w\| \left( \|v_x\| + \sqrt{\mu h^{-1}}|v| \right). \tag{2.16}
\]
if (2.13) holds.

Proof. From (2.9a) and the periodic boundary condition, we have
\[
\mathcal{H}(f(u), v) = \sum_{j=1}^{N} \left\{ (f(u), v_x)_j - \hat{f}(u)_{j+\frac{1}{2}} v^{-}_{j+\frac{1}{2}} + \hat{f}(u)_{j-\frac{1}{2}} v^{+}_{j-\frac{1}{2}} \right\}
= \sum_{j=1}^{N} \left\{ (f(u), v_x)_j + \hat{f}(u)_{j-\frac{1}{2}} [v]_{j-\frac{1}{2}} \right\}. \tag{2.17}
\]
Integrating by parts yields
\[
\mathcal{H}(f(u), v) = \sum_{j=1}^{N} \left\{ -(f(u)_x, v)_j + f(u_{j+\frac{1}{2}}^-)v_{j+\frac{1}{2}}^- - f(u_{j-\frac{1}{2}}^+)v_{j-\frac{1}{2}}^+ + \hat{f}(u)_{j-\frac{1}{2}}[v]_{j-\frac{1}{2}} \right\}
\]
\[
= \sum_{j=1}^{N} \left\{ -(f'(u)u_x, v)_j + f(u_{j-\frac{1}{2}}^-)v_{j-\frac{1}{2}}^- - f(u_{j+\frac{1}{2}}^+)v_{j+\frac{1}{2}}^+ + \hat{f}(u)_{j-\frac{1}{2}}[v]_{j-\frac{1}{2}} \right\}
\]
\[
= \sum_{j=1}^{N} (\theta_1^j + \theta_2^j + \theta_3^j + \theta_4^j).
\] (2.18)

Noting that
\[
\theta_2^j + \theta_3^j + \theta_4^j = (f(u^-) - f(u^+))v^- - f(u^+)[v] + \hat{f}(u)[v]
\]
\[
= -f'(\sigma_1)[u]v^- + (\hat{f}(u^-) + \hat{f}(u^+))[v],
\]
where the last equality follows from the mean-value theorem, with \(\sigma_1 = a_1u^- + (1-a_1)u^+\) for some \(a_1 \in [0, 1]\), and the consistency of the numerical flux \(\hat{f}\). Here we have dropped the subscript \(j-\frac{1}{2}\) for simplicity of notation. By the Lipschitz continuity of \(\hat{f}\), we have
\[
|\hat{f}(u^-) - \hat{f}(u^+)| \leq C_f [|u|].
\]
Then using the inverse inequality (2.16) we have
\[
|\theta_2^j + \theta_3^j + \theta_4^j| \leq C_f \sqrt{\mu h^{-1}} [\|u\|_{I_{j-\frac{1}{2}}} + \|v\|_{I_j}].
\] (2.19)
Moreover, the simple use of Cauchy-Schwarz inequality and (2.13b) gives rise to
\[
|\theta_1^j| \leq C_f \|u_x\|_{I_j} \|v\|_{I_j}.
\] (2.20)
As a result, summing the above two estimates over \(j = 1, \cdots, N\), we get (2.15).

Next we will prove (2.15). From (2.17) we have
\[
\mathcal{D}(u, w; v) = \sum_{j=1}^{N} \left\{ (f(u) - f(w), v_x)_j + (\hat{f}(u) - \hat{f}(w))_{j-\frac{1}{2}}[v]_{j-\frac{1}{2}} \right\} = \sum_{j=1}^{N} (\theta_5^j + \theta_6^j).
\] (2.21)
It follows from the mean-value theorem and the Cauchy-Schwarz inequality that
\[
|\theta_5^j| = |(f'(\sigma_2)(u-w), v_x)_j| \leq C_f \|u-w\|_{I_j} \|v_x\|_{I_j},
\] (2.22)
where \(\sigma_2 = a_2 u + (1-a_2)w\) for some \(a_2 \in [0, 1]\). From (2.18) we get
\[
|\theta_6^j| \leq C_f \|u^- - w^-\|_{I_{j-\frac{1}{2}}} + |u^+ - w^+\|_{I_{j-\frac{1}{2}}}[v]_{j-\frac{1}{2}}.
\]
Thus by the inverse inequality (2.16) we have
\[
|\theta_6^j| \leq C_f \sqrt{\mu h^{-1}} (\|u-w\|_{I_{j-1}} + \|u-w\|_{I_j}) \|v\|_{j-\frac{1}{2}}.
\] (2.23)
As a consequence, by summing (2.22) and (2.23) over \(j = 1, \cdots, N\), we obtain (2.15).
3. IMEX RK LDG schemes

In this paper we would like to consider the LDG spatial discretization coupled with three specific IMEX Runge-Kutta schemes up to third order which are presented in [14].

3.1. Fully discrete schemes

Let \( \{ t^n = n\tau \}^{M}_{n=0} \) be the uniform partition of the time interval \([0, T]\), with time step \( \tau \). The time step could actually change from step to step, but in this paper we take the time step as a constant for simplicity. Given \( u^n \), hence \((u^n, q^n)\), we would like to find the numerical solution at the next time level \( t^{n+1} \), (maybe through several intermediate stages \( t^{n,\ell} \)), by the following IMEX RK methods.

The LDG scheme with the first order IMEX time-marching scheme, where the convection part is treated by the forward Euler method and the diffusion part is treated by the backward Euler method, is given in the following form:

\[
\begin{align*}
(u^{n+1}, v) &= (u^n, v) + \tau \mathcal{H}(f(u^n), v) + \tau \mathcal{L}(q^{n+1}, v); \\
(q^{n+1}, r) &= k(u^{n+1}, r),
\end{align*}
\]  

(3.1a)

(3.1b)

for any function \((v, r) \in V_h \times V_h\).

The LDG scheme with the second order IMEX time marching scheme given in [1] is:

\[
\begin{align*}
(u^{n,1}, v) &= (u^n, v) + \gamma \tau \mathcal{H}(f(u^n), v) + \gamma \tau \mathcal{L}(q^{n,1}, v), \\
(u^{n+1}, v) &= (u^n, v) + \delta \tau \mathcal{H}(f(u^n), v) + (1 - \delta)\tau \mathcal{H}(f(u^{n,1}), v) \\
&\quad + (1 - \gamma)\tau \mathcal{L}(q^{n,1}, v) + \gamma \tau \mathcal{L}(q^{n+1}, v); \\
(q^{n,\ell}, r) &= k(u^{n,\ell}, r), \quad \ell = 1, 2,
\end{align*}
\]  

(3.2a)

(3.2b)

(3.2c)

for any function \((v, r) \in V_h \times V_h\), where \( \gamma = 1 - \sqrt{2} \) and \( \delta = 1 - \frac{1}{\sqrt{2}} \). Here \( w^{n,2} = w^{n+1} \).

The LDG scheme with the third order IMEX time marching scheme proposed in [3] reads: for any function \((v, r) \in V_h \times V_h\),

\[
\begin{align*}
(u^{n,\ell}, v) &= (u^n, v) + \tau \sum_{i=0}^{3} (a_{\ell i} \mathcal{H}(f(u^{n,i}), v) + \hat{a}_{\ell i} \mathcal{L}(q^{n,i}, v)), \quad \text{for } \ell = 1, 2, 3, \\
(u^{n+1}, v) &= (u^n, v) + \tau \sum_{i=0}^{3} (b_{\ell i} \mathcal{H}(f(u^{n,i}), v) + \hat{b}_{\ell i} \mathcal{L}(q^{n,i}, v)); \\
(q^{n,\ell}, r) &= k(u^{n,\ell}, r), \quad \ell = 1, 2, 3,
\end{align*}
\]  

(3.3a)

(3.3b)

(3.3c)
where the coefficients are given in the following tabular

\[
\begin{array}{c|cccc|cccc|c}
\ell & \frac{\gamma}{2} - \alpha_1 & \alpha_1 & 0 & 0 & 0 & \gamma & 0 & 0 & \bar{\alpha}_\ell \\
1 & 0 & 1 - \alpha_2 & \alpha_2 & 0 & 0 & \bar{\beta}_1 & \beta_2 & \gamma & b_1 \\
\end{array}
\]

(3.4)

The left half of the tabular lists \(a_\ell i\) and \(b_i\), with the columns from left to right corresponding to \(i = 0, 1, 2, 3\), and the first three rows from top to bottom corresponding to \(\ell = 1, 2, 3\). Similarly, the right half lists \(\bar{a}_\ell i\) and \(\bar{b}_i\). In (3.4), \(\gamma \approx 0.435866521508459\), is the middle root of \(6x^3 - 18x^2 + 9x - 1 = 0\). Also, \(\beta_1 = -\frac{3}{2}\gamma^2 + 4\gamma - \frac{1}{4}, \beta_2 = \frac{3}{2}\gamma^2 - 5\gamma + \frac{5}{4}\). The parameter \(\alpha_1\) is chosen as \(-0.35\) in (3) and \(\alpha_2 = \frac{1 - 2\gamma^2 - \gamma^2}{\gamma(1 - 2\gamma)}\).

In the next two subsections we will consider the stability analysis and error estimates for the above schemes. As an example, we pay our attention to the third order time-marching, namely, the scheme [3].

3.2. Stability analysis

From Lemmas 2.4 and 2.5 we can see that, for the nonlinear convection term, the operator \(H\) also has the so called “non-positivity” property and the two similar boundedness properties as in the linear case. Hence conceptually we can get the same stability property for the nonlinear problems as what we got in [14] along similar arguments.

However, the procedure to deal with the linear convection terms in [14] cannot be used to handle the nonlinear convection terms directly. Because in the linear case, besides the terms which are the differences of solutions at two different time levels, there are also terms which are convex combinations of solutions at three time levels, for example, \(H(u^{n-1} - 2u^{n-1} + u^n, v)\). The estimate for such terms is easy in the linear case, but if we change \(w^n, f\) into \(f(w^n, f)\), we cannot find a similar estimate. In such nonlinear case we would need to divide this term into \(D(u^{n-2}, u^{n-1}; v) - D(u^{n-1}, u^n; v)\) and then use the property (2.16) to estimate it. Also, there is a non-positive term \(H(u^{n-2} - 2u^{n-1}, u^{n-2} - 2u^{n-1})\) in the linear case, but \(H(f(u^{n-2}) - 2f(u^{n-1}), u^{n-2} - 2u^{n-1})\) is not necessarily non-positive. Therefore, we would need to treat the nonlinear convection part in a different manner.

**Theorem 3.1.** There exists a positive constant \(\tau_0\) independent of \(h\), such that if \(\tau \leq \tau_0\), then the solution of scheme (3.3) satisfies

\[
\|u^n\| \leq \|u^0\|, \quad \forall n,
\]

(3.5)

if (2.13) holds.

**Proof.** For the convenience of analysis, we follow [14] to introduce a series of notations

\[
\begin{align*}
E_1w^n &= w^{n,1} - w^n, & E_2w^n &= w^{n,2} - 2w^{n,1} + w^n, \\
E_3w^n &= 2w^{n,3} + w^{n,2} - 3w^{n,1}, & E_4w^n &= w^{n+1} - w^{n,3},
\end{align*}
\]

(3.6)
for arbitrary $w$, and rewrite the scheme (3.3) into the following compact form

$$\langle E_{\ell}u^n, v \rangle = \Phi_{\ell}(u^n, v) + \Psi_{\ell}(q^n, v), \quad \text{for } \ell = 1, 2, 3, 4; \quad (3.7a)$$

$$\langle q^{n,\ell}, r \rangle = K(u^{n,\ell}, r), \quad \text{for } \ell = 1, 2, 3 \quad (3.7b)$$

where $u^n = (u^n, u^{n,1}, u^{n,2}, u^{n,3})$ and $q^n = (q^{n,1}, q^{n,2}, q^{n,3})$, and

$$\Phi_{\ell}(u^n, v) = \sum_{i=0}^{3} \delta_{\ell i} \tau H(f(u^{n,i}), v), \quad \text{for } \ell = 1, 2, 3 \quad (3.8)$$

$$\Psi_{\ell}(q^n, v) = \theta_{\ell 1} L(q^{n,1}, v) + \theta_{\ell 2} \tau L(q^{n,2} - 2q^{n,1}, v) + \theta_{\ell 3} \tau L(q^{n,3}, v), \quad \text{for } \ell = 1, 2, 3, 4 \quad (3.9)$$

for $\ell = 1, 2, 3, 4$. The coefficients $\delta_{\ell i}$ and $\theta_{\ell i}$ are listed in Table 1. See [14] for more details.

Along the same line as the proof in [14], we take the test functions $v = u^{n,1}, u^{n,2} - 2u^{n,1}, u^{n,3}$ and $2u^{n+1}$ in (3.7), for $\ell = 1, 2, 3, 4$, respectively. Adding them together, we get the energy equation

$$\|u^{n+1}\|^2 - \|u^n\|^2 + S = T_c + T_d, \quad (3.10)$$

where

$$S = \frac{1}{2} \left( \|E_1 u^n\|^2 + \|E_2 u^n\|^2 + \|E_3 u^n\|^2 + \|E_4 u^n\|^2 + 2\|E_5 u^n\|^2 \right) \quad (3.11a)$$

is the stability coming from the time-marching, with $E_3 u^n = u^{n,3} + u^{n,2} - 2u^{n,1}$ and $E_4 u^n = u^{n,3} - u^{n,1}$. Furthermore,

$$T_c = \Phi_1(u^n, u^{n,1}) + \Phi_2(u^n, u^{n,2} - 2u^{n,1}) + \Phi_3(u^n, u^{n,3}) + 2\Phi_4(u^n, u^{n+1}), \quad (3.11b)$$

$$T_d = \Psi_1(q^n, u^{n,1}) + \Psi_2(q^n, u^{n,2} - 2u^{n,1}) + \Psi_3(q^n, u^{n,3}) + 2\Psi_4(q^n, q^{n+1}), \quad (3.11c)$$

are given in the same form as in [14]. We will consider them one by one.

Denote $w^T = (q^{n,1}, q^{n,2} - 2q^{n,1}, q^{n,3})$, and $\|w\|^2 = \|q^{n,1}\|^2 + \|q^{n,2} - 2q^{n,1}\|^2 + \|q^{n,3}\|^2$. Noting that

$$L(q_1, q_2) = -K(q_2, q_1) = -(q_2, q_1) = -(q_1, q_2) \quad (3.12)$$

Table 1: The coefficients $\delta_{\ell i}$ and $\theta_{\ell i}$ in [14] and [15].

holds for any pairs \((u_1, q_1)\) and \((u_2, q_2)\), owing to Lemma 2.1 and (2.10b). By using (3.12) we get
\[
T_d = -\tau \int_\Omega w^T A w \, dx, \tag{3.13}
\]
where
\[
A = \frac{1}{2} \begin{pmatrix}
2\theta_{11} & \theta_{21} & \theta_{31} \\
\theta_{21} & 2\theta_{22} & \theta_{32} \\
\theta_{31} & \theta_{32} & 2\theta_{33}
\end{pmatrix}. \tag{3.14}
\]
Since all the principal minor determinants of \(A\) are positive, we can conclude that \(A\) is positive definite. In fact we can show in the same way that
\[
T_d \leq -\frac{\gamma}{4} \tau \|w\|^2 \leq 0. \tag{3.15}
\]

The estimate to the remaining term \(T_c\) is a little more complicated, due to the nonlinearity of the flux. From (3.8) and after some algebraic manipulations we get
\[
T_c = T_c^{(1)} + T_c^{(2)} + T_c^{(3)}, \tag{3.16}
\]
where
\[
T_c^{(1)} = \tau (\delta_{10} - \delta_{20} - \delta_{21}) \mathcal{H}(f(u^{n,1}), u^{n,1}) + \tau \sum_{i=0}^2 \delta_{3i} \mathcal{H}(f(u^{n,3}), u^{n,3}), \tag{3.17a}
\]
\[
T_c^{(2)} = \tau (\delta_{20} + \delta_{21}) \mathcal{H}(f(u^{n,1}), u^{n,2} - u^{n,1}) + \tau \sum_{i=1}^3 \delta_{4i} \mathcal{H}(f(u^{n,i}), u^{n+1} - u^{n,3}), \tag{3.17b}
\]
\[
T_c^{(3)} = -\tau \delta_{10} \mathcal{D}(u^{n,1}, u^{n,1}; u^{n,1}) - \tau \delta_{20} \mathcal{D}(u^{n,1}, u^{n,2} - 2u^{n,1}) - \tau \delta_{20} \mathcal{D}(u^{n,1}, u^{n,2}; u^{n,3}) + \tau (\delta_{32} + 2\delta_{32}) \mathcal{D}(u^{n,2}, u^{n,1}; u^{n,3}) + \tau \left(2\delta_{43} - \sum_{i=0}^2 \delta_{3i}\right) \mathcal{D}(u^{n,3}, u^{n,1}; u^{n,3}). \tag{3.17c}
\]

It is easy to check that both coefficients \((\delta_{10} - \delta_{20} - \delta_{21})\) and \(\sum_{i=0}^2 \delta_{3i}\) in (3.17a) are positive, so owing to Lemma 2.4 we have \(T_c^{(1)} \leq 0\). Noticing that all the coefficients in the expressions of \(T_c^{(2)}\) and \(T_c^{(3)}\) are bounded, we will utilize (2.15) and (2.16) to estimate \(T_c^{(2)}\) and \(T_c^{(3)}\), respectively.

For example, if we denote the first and the second term of \(T_c^{(2)}\) by \(V_1\) and \(V_2\), respectively, then from (2.15), Lemma 2.3 and the triangle inequality we get
\[
V_1 \leq C_f \tau (\|u_x^{n,1}\| + \sqrt{\mu h^{-1}}\|u^{n,1}\|) \|u^{n,2} - u^{n,1}\|
\leq C_f C_\mu \tau \sqrt{d} \|q^{n,1}\| \|u^{n,2} - u^{n,1}\|
\leq C_f C_\mu \tau \sqrt{d} \|q^{n,1}\| (\|E_2 u^n\| + \|E_1 u^n\|),
\]

11
and
\[ V_2 \leq C_f \tau \sum_{\ell=1}^{3} (\| u_{x,\ell}^{n} \| + \sqrt{\mu h^{-1}}|u_{x,\ell}^{n}|)\| E_4 u^n \| \leq \frac{C_f C_H}{\sqrt{d}} \tau \sum_{\ell=1}^{3} \| q_{\ell}^{n} \| \| E_4 u^n \|. \]

Similarly, from (2.16), Lemma 2.3 and the triangle inequality we have
\[ T_c^{(3)} \leq \frac{C_f C_H}{\sqrt{d}} \tau (\| E_1 u^n \| + \| E_2 u^n \| + \| E_{32} u^n \|) (\| q_1^{n} \| + \| q_2^{n} - 2q_1^{n} \| + \| q_3^{n} \|). \]

Hence we can derive
\[ T_c \leq \frac{C_f C_H}{\sqrt{d}} \tau S^2 \| w \| \leq \varepsilon \tau \| w \|^2 + \frac{C_f^2 C_H^2}{4d \varepsilon} \tau S, \] (3.18)
by using Young's inequality, where \( \varepsilon > 0 \) is arbitrary. Noting that the value of \( C_f \) may be several times of the value \( C_f \) in (2.15) and (2.16), but we use the same notation as we mentioned in Remark 1, just for the sake of simplicity.

We would like to take \( \varepsilon = \frac{1}{2} \), then owing to (3.10), (3.15) and (3.18) we have
\[ \| u^{n+1} \|^2 - \| u^n \|^2 + S \leq \frac{C_f^2 C_H^2}{d \gamma} \tau S, \] (3.19)
Thus \( \| u^{n+1} \| \leq \| u^n \| \) if \( \tau \leq \tau_0 = \frac{d \gamma}{C_f C_H^2} \). This completes the proof of this theorem. \( \square \)

**Remark 2.** From the proof we can see that \( \tau_0 \) is proportional to \( d/C_f^2 \), which is the similar as the linear case; see [14]. We use the notation \( \tau_0 \) as a generic time step bound for the stability analysis and error estimates in this paper, it may have different values in each occurrence.

### 3.3. Error estimate

In this subsection we would like to obtain the optimal error estimate. To this end, we would like to assume that the exact solution \( U(x, t) \) is sufficiently smooth, for example,
\[ U \in L^\infty(0, T; H^{k+2}), \quad D_t U \in L^\infty(0, T; H^{k+1}), \quad \text{and} \quad D^4_t U \in L^\infty(0, T; L^2), \]
(3.20)
where \( D^\ell_t U \) is the \( \ell \)-th order time derivative of \( U \), and \( L^\infty(0, T; H^s(D)) \) represents the set of functions \( v \) such that \( \max_{0 \leq t \leq T} \| v(\cdot, t) \|_{H^s(D)} < \infty \).

Furthermore, we would like to assume the flux function \( f \) in (2.1) is smooth enough, for example, \( f \in C^{k+3} \). In particular, we would like to assume
\[ |f'(p)|, |f''(p)| \leq C_f, \] (3.21)
for arbitrary \( p \in \mathbb{R} \). For a given initial condition, this assumption is reasonable with the original or a suitably modified flux \( f \), due to the maximum principle; see [20] for more details.

The main result is stated in the following theorem.
Theorem 3.2. Let $u$ be the numerical solution of scheme (3.3). The finite element space $V_h$ is the space of piecewise polynomials with degree $k > 1$ on the quasi-uniform triangulations of $\Omega = (a, b)$. Let $U(x, t)$ be the exact solution of problem (2.1) which satisfies the smoothness assumption (3.20), then there exist positive constants $h_0$ and $\tau_0$, such that if $h \leq h_0$ and $\tau \leq \tau_0$, then there holds the following error estimate
\[
\max_{n\tau \leq T} \|U(x, t^n) - u^n\| \leq C(h^{k+1} + \tau^3), \tag{3.22}
\]
where $T$ is the final computing time and the bounding constant $C > 0$ is independent of $h$ and $\tau$.

The proof of this theorem is lengthy and technical. We split this process into three steps.

**Step 1: reference functions**

Based on the idea of [12], we would like to let $U^0 = U_0(x)$, and define $(U^{n,\ell}(x), Q^{n,\ell}(x))$ as the solution of the following third order IMEX time discrete problem:
\[
U^{n,\ell} = U^n + \tau \sum_{i=0}^{3} (-a_{\ell i} f(U^{n,i})_x + \hat{a}_{\ell i} \sqrt{d}(Q^{n,i})_x), \quad \text{for } \ell = 1, 2, 3, \tag{3.23a}
\]
\[
U^{n+1} = U^n + \tau \sum_{i=0}^{3} (-b_i f(U^{n,i})_x + \hat{b}_i \sqrt{d}(Q^{n,i})_x); \tag{3.23b}
\]
for arbitrary $n\tau \leq T$, where we have dropped the argument $x$ for simplicity of notation, the coefficients $a_{\ell i}, \hat{a}_{\ell i}$ and $b_i, \hat{b}_i$ were given in (3.4), and
\[
Q^{n,\ell} = \sqrt{d}(U^{n,\ell})_x, \quad \text{for } \ell = 1, 2, 3. \tag{3.23c}
\]

Since $D_4^4 U \in L^\infty(0, T; L^2)$, we can get that the error between the exact solution and the time discrete solution of (3.23) is bounded in the form
\[
\|U^n(x) - U^n(x)\| \leq C \tau^3, \quad \forall n\tau \leq T, \tag{3.24}
\]
where $C$ only depends on the final computing time $T$. Furthermore, we can follow the similar line as the proof of Theorem 3.1 in [12] to prove that
\[
\|U^{n,\ell}\|_{H^{k+1}} \leq C, \quad \|Q^{n,\ell}\|_{H^{k+1}} \leq C, \quad \text{and} \quad \|E_{\ell+1} U^n\|_{H^{k+1}} \leq C \tau, \tag{3.25}
\]
for any $n$ and $\ell = 0, 1, 2, 3$ under consideration, if the exact solution $U(x, t)$ is assumed to be in $H^{k+2}$ and the flux function $f$ is assumed to be in $C^{k+3}$. We omit the detailed proof to save space.

It is easy to verify that these reference functions satisfy the following variational forms
\[
(E_{\ell} U^n, v) = \Phi_{\ell}(U^n, v) + \Psi_{\ell}(Q^n, v), \quad \text{for } \ell = 1, 2, 3, 4; \tag{3.26a}
\]
\[
(Q^{n,\ell}, r) = K(U^{n,\ell}, r), \quad \text{for } \ell = 1, 2, 3, \tag{3.26b}
\]
for any \((v, r) \in H^1(T_h) \times H^1(T_h)\), which is very analogous to scheme \((3.7)\). Here we denote \(U^n = (U^n, U^{n,1}, U^{n,2}, U^{n,3})\) and \(Q^n = (Q^{n,1}, Q^{n,2}, Q^{n,3})\).

**Step 2: error presentation, error equations and energy equations**

For the purpose of estimating the error between the exact solution and the numerical solution \(U(x, t^n) - u^n\), we only need to estimate \(U^n - u^n\), the error between the solution of \((3.28)\) and the numerical solution.

Towards this end, at each time stage we denote the error between the discrete solution and the numerical solution by

\[
e^{n,\ell} = (e^{n,\ell}_u, e^{n,\ell}_q) = (U^{n,\ell} - u^{n,\ell}, Q^{n,\ell} - q^{n,\ell}).
\]

As the standard treatment in finite element analysis, we would like to divide the error in the form \(e^{n,\ell} = \xi^{n,\ell} - \eta^{n,\ell}\), where

\[
\begin{align*}
\xi^{n,\ell} &= (\xi^{n,\ell}_u, \xi^{n,\ell}_q) = (\pi^h U^{n,\ell} - u^{n,\ell}, \pi^h Q^{n,\ell} - q^{n,\ell}) , \\
\eta^{n,\ell} &= (\eta^{n,\ell}_u, \eta^{n,\ell}_q) = (\pi^h U^{n,\ell} - U^{n,\ell}, \pi^h Q^{n,\ell} - Q^{n,\ell}).
\end{align*}
\]

(3.27)

It follows from the linearity of projections \(\pi^h\) and \((3.28)\) that the stage projection errors and their evolutions satisfy

\[
\begin{align*}
\|\eta^{n,\ell}_u\| + h^{1/2}\|\eta^{n,\ell}_u\|_{\Gamma_h} + h^{1/2}\|\eta^{n,\ell}_q\|_{\infty} + \|\eta^{n,\ell}_q\| &\leq C h^{k+1}, \\
\|\mathcal{E}_{\ell+1}\eta^{n,\ell}_u\| + h^{1/2}\|\mathcal{E}_{\ell+1}\eta^{n,\ell}_q\|_{\Gamma_h} &\leq C h^{k+1} \tau,
\end{align*}
\]

(3.28a)

(3.28b)

where the bounding constant \(C > 0\) depends solely on the smoothness of the solution \(U^{n,\ell}\) and \(Q^{n,\ell}\), which was given in \((3.29)\), independent of \(n, h\) and \(\tau\).

In what follows we will focus on the estimate to the error in the finite element space. Towards the goal of obtaining the final estimate for \(\xi^n_u\), we would like first to establish the energy equation, following the similar line as the previous stability analysis.

We subtracting the variational forms in \((3.29)\) from those in scheme \((3.7)\), at the same order. Since the projection error related terms in \(\Psi_\ell\) and \(K\) vanish by Lemma \((3.2)\), we obtain the following error equations

\[
\begin{align*}
(\mathcal{E}_\ell \xi^n_u, v) &= \Phi_\ell(U^n, v) - \Phi_\ell(u^n, v) + \Psi_\ell(\xi^n_q, v) + (\mathcal{E}_\ell \eta^n_u, v), \quad \text{for } \ell = 1, 2, 3, 4; \\
(\xi^n_u, r) &= K(\xi^n_u, r) + (\eta^n_u, r), \quad \text{for } \ell = 1, 2, 3,
\end{align*}
\]

(3.29a)

(3.29b)

where \(\xi^n_u = (\xi^{n,1}_u, \xi^{n,2}_u, \xi^{n,3}_u, \xi^{n,4}_u)\).

Taking \(v = \xi^{n,1}_u, \xi^{n,2}_u - 2\xi^{n,1}_u, \xi^{n,3}_u\) and \(2\xi^{n+1}_u\) in \((3.29a)\), for \(\ell = 1, 2, 3, 4\) respectively, and adding them together, we obtain the energy equation

\[
\|e^{n+1}_u\|^2 - \|\xi^n_u\|^2 + \tilde{S} = \tilde{T}_c + \tilde{T}_d + \tilde{T}_p,
\]

(3.30)

where

\[
\tilde{S} = \frac{1}{2} \left( \|\mathcal{E}_1 \xi^n_u\|^2 + \|\mathcal{E}_2 \xi^n_u\|^2 + \|\mathcal{E}_{31} \xi^n_u\|^2 + \|\mathcal{E}_{32} \xi^n_u\|^2 + 2\|\mathcal{E}_4 \xi^n_u\|^2 \right),
\]

(3.31a)
\[ T_c = \sum_{\ell=1}^{4} (\Phi_{\ell}(U^n, v_\ell) - \Phi_{\ell}(u^n, v_\ell)), \quad T_d = \sum_{\ell=1}^{4} \Psi_{\ell}(\xi^{n,\ell}_u, v_\ell), \quad T_p = \sum_{\ell=1}^{4} (E_{\ell} \eta^{n,\ell}_u, v_\ell). \]  

(3.31b)

Here and below we use the simplified notations

\[ v_1 = \xi^{n,1}_u, \quad v_2 = \xi^{n,2}_u - 2\xi^{n,1}_u, \quad v_3 = \xi^{n,3}_u, \quad \text{and} \quad v_4 = 2\xi^{n+1}_u. \]

**Step 3: energy analysis**

To derive the final error estimates, we would like to follow [21] and make the a priori assumption for \(m\), if \(m \tau \leq T\):

\[ \|e^{n,\ell}_u\|_{\infty} \leq C_0 h, \quad \text{for} \quad n \leq m, \ell = 0, 1, 2, 3, \]  

(3.32)

where \(C_0\) is a positive constant independent of \(m, h, \tau\) and \(u\).

**Lemma 3.3.** Let \(U^{n,\ell}\) be the solution of (3.23) satisfying the smoothness (3.25), and \(u^{n,\ell}\) be the solution of scheme (3.3), then for arbitrary \(v \in V_h\) we have

\[ |D(U^{n,\ell}, u^{n,\ell}; v)| \leq C_f (\|\xi^{n,\ell}_u\| + h^{k+1}) (\|v_x\| + \sqrt{\mu h^{-1}}|v|). \]  

(3.33)

**Proof.** The proof for this lemma is the similar as that for (2.16). The projection error approximation property (3.28a) is used in the proof. We skip the details to save space. \(\square\)

**Lemma 3.4.** There exist positive constant \(C\) independent of \(n, h, \tau\), and \(\tau_0\) independent of \(h\), such that, if \(\tau \leq \tau_0\), then

\[ \|\xi^{n+1}_u\|^2 - \|\xi^{n}_u\|^2 \leq C\tau \sum_{\ell=0}^{4} \|\xi^{n,\ell}_u\|^2 + C(h^{2k+2}\tau + h^{2k}\tau^4), \]  

(3.34)

if the a priori assumption (3.32) holds, where \(\xi^{n,0}_u = \xi^{n}_u\) and \(\xi^{n,4}_u = \xi^{n+1}_u\).

**Proof.** We only need to estimate the three terms on the right-hand side of the energy equation (3.30). A simple use of the Cauchy-Schwarz inequality, the Young’s inequality and (3.33) yields

\[ T_p \leq \tau \sum_{\ell=1}^{4} \|\xi^{n,\ell}_u\|^2 + \frac{C}{\tau} \sum_{\ell=1}^{4} \|E_{\ell} \eta^{n,\ell}_u\|^2 \leq \tau \sum_{\ell=1}^{4} \|\xi^{n,\ell}_u\|^2 + Ch^{2k+2}\tau. \]  

(3.35)

The estimate for \(T_d\) is the similar as the one for \(T_d\) in the stability analysis. Similar as the property (3.12) we have

\[ \mathcal{L}(\xi^1_q, \xi^1_u) = -\mathcal{K}(\xi^2_q, \xi^1_q) = - (\xi^1_q, \xi^1_q) + (\eta^2_q, \xi^1_q), \]  

(3.36)
for any pairs of \( (\xi_1^u, \xi_1^q) \) and \( (\xi_2^u, \xi_2^q) \), due to Lemma 2.1 and (3.29b). By using property (3.36) and the Cauchy-Schwarz inequality, the Young’s inequality and (3.28a), we can derive, along the similar line as the estimate for \( \tilde{T}_d \) in (3.11c),

\[
\tilde{T}_d \leq - \left( \frac{\gamma}{4} - \varepsilon \right) \tau \| \tilde{w} \|^2 + C_\varepsilon h^{2k+2} \tau, \quad (3.37)
\]

for arbitrary \( \varepsilon > 0 \), where \( C_\varepsilon \) is a positive constant only depending on \( \varepsilon \), and

\[
\| \tilde{w} \|^2 = \| \xi_1^q \|^2 + \| \xi_2^q - 2 \xi_1^q \|^2 + \| \xi_3^q \|^2.
\]

The procedure of estimating \( \tilde{T}_c \) is more complicated than the one for estimating \( T_c \) in the stability analysis. From (3.8) we have

\[
\tilde{T}_c = Z_1 + Z_2,
\]

where

\[
Z_1 = \tau \sum_{\ell=1}^{3} \sum_{i=0}^{3} \delta_{\ell,i} D(U^{n,i}, \xi^u_{n,i}; v_{\ell}) + 2\tau \sum_{i=0}^{3} \delta_{4,i} D(U^{n,i}, \xi^u_{n,i}; v_3), \quad (3.38a)
\]

\[
Z_2 = 2\tau \sum_{i=0}^{3} \delta_{4,i} D(U^{n,i}, \xi^u_{n,i}; \xi^u_{n,i}). \quad (3.38b)
\]

Let us consider them one by one. A direct use of Lemma 3.3 gives rise to

\[
Z_1 \leq C_f \tau \sum_{\ell=0}^{3} (\| \xi^u_{n,\ell} \| + h^{k+1}) R,
\]

where

\[
R = \sum_{i=1}^{3} ((v_i)_x + \sqrt{\mu h^{-1}} [v_i]).
\]

Noticing that for any pair of \( (\xi^u_{n,\ell}, \xi^q_{n,\ell}) \) there holds

\[
\| (v_2)_x \| + \sqrt{\mu h^{-1}} [v_2] \leq C_\mu \sqrt{d} (\| \xi^q_{n,2} - 2 \xi^q_{n,1} \| + \| \eta^q_{n,2} - 2 \eta^q_{n,1} \|), \quad (3.39)
\]

which is similar to (2.12) and the proof is also similar. Moreover, by the linear structure of (3.29b), (3.39) also holds for any linear combination of any pairs of \( (\xi^u_{n,\ell}, \xi^q_{n,\ell}) \), for example, for \( v_2 = \xi^u_{n,2} - 2 \xi^u_{n,1} \), we have

\[
\| (v_2)_x \| + \sqrt{\mu h^{-1}} [v_2] \leq C_\mu \sqrt{d} (\| \xi^q_{n,2} - 2 \xi^q_{n,1} \| + \| \eta^q_{n,2} - 2 \eta^q_{n,1} \|).
\]

Hence by (3.39) and (3.28a) we have

\[
R \leq \frac{C_\mu}{\sqrt{d}} (\| \xi^q_{n,1} \| + \| \xi^q_{n,2} - 2 \xi^q_{n,1} \| + \| \xi^q_{n,3} \| + h^{k+1}).
\]

Then a simple use of the Young’s inequality yields

\[
Z_1 \leq \frac{C_f^2 C^2}{d} \tau \sum_{\ell=0}^{3} \| \xi^u_{n,\ell} \|^2 + \varepsilon \tau \| \tilde{w} \|^2 + \left( \frac{C_f^2 C^2}{d} + \frac{C_\mu}{\sqrt{d}} \right) h^{2k+2} \tau, \quad (3.40)
\]
for arbitrary $\varepsilon > 0$. Here $C_f$ depends on $\varepsilon$. To obtain the sharp estimate for $Z_2$, we would like to start with the following identity

$$Z_2 = 2\delta_{42} \tau \left[ D(U^{n,2}, u^{n,2}; E_4 \xi_u^n) - D(U^{n,1}, u^{n,1}; E_4 \xi_u^n) \right]$$

\[ + 2\delta_{43} \tau \left[ D(U^{n,3}, u^{n,3}; E_4 \xi_u^n) - D(U^{n,1}, u^{n,1}; E_4 \xi_u^n) \right], \tag{3.41} \]

where the differences of reference functions play critical roles. By the aid of an important quantity $\alpha(\cdot, \cdot)$ introduced in [21] which measures the numerical viscosity, and after a long and technical analysis, we can derive

$$Z_2 \leq C \tau^3 \sum_{\ell=0}^{3} \| \xi_u^{n,\ell} \|^2 + \varepsilon \tau \| \tilde{w} \|^2 + C(h^{2k+2}\tau + h^{2k}\tau^4)$$

\[ + \left( C_7^2 \tau + C_7^2 C_6^2 \tau + \frac{C_7^2 C_6^2}{d} \tau + \varepsilon \right) \| E_4 \xi_u^n \|^2, \tag{3.42} \]

for arbitrary $\varepsilon > 0$. The definition of $\alpha(\cdot, \cdot)$ and the detailed proof are left to the Appendix, and we continue to obtain the final error estimate.

We choose $\varepsilon$ small enough and letting $\tau \leq \tau_0$, where $\tau_0$ is a positive constant independent of $h$, such that the coefficient in front of $\| E_4 \xi_u^n \|^2$ is not over $1/2$.

Then from (3.42) and (3.43) we have

$$T'_c \leq C \tau \sum_{\ell=0}^{3} \| \xi_u^{n,\ell} \|^2 + 2\varepsilon \tau \| \tilde{w} \|^2 + \frac{1}{2} \| E_4 \xi_u^n \|^2 + C(h^{2k+2}\tau + h^{2k}\tau^4). \tag{3.43}$$

Consequently, by (3.40), (3.43), (3.37) and (3.43) we have

$$\| \xi_u^{n+1} \|^2 - \| \xi_u^n \|^2 \leq C \tau \sum_{\ell=0}^{4} \| \xi_u^{n,\ell} \|^2 - \left( \gamma \frac{1}{4} - 3\varepsilon \right) \| \tilde{w} \|^2 + C(h^{2k+2}\tau + h^{2k}\tau^4).$$

Hence, we are led to the desired result (3.34) if $\varepsilon \leq \gamma \frac{1}{12}$. □

The estimate for the intermediate stage values $\| \xi_u^{n,\ell} \|$ emerging in (3.44) can be obtained along the similar argument as the proof for Lemma 3.4. So we omit the details and only state it in the following lemma.

**Lemma 3.5.** There exist positive constant $C$ independent of $n, h, \tau$, and $\tau_0$ independent of $h$, such that, if $\tau \leq \tau_0$, then

$$\| \xi_u^{n,\ell} \|^2 \leq C \left( \| \xi_u^n \|^2 + h^{2k+2}\tau \right), \quad \text{for} \quad \ell = 1, 2, 3. \tag{3.44}$$

Combining Lemmas 3.4 and 3.5 and by the aid of the discrete Gronwall’s inequality, we can derive

$$\| \xi_u^n \|^2 \leq e^{Cn\tau} \left( \| \xi_u^0 \|^2 + h^{2k+2} + h^{2k}\tau^3 \right), \tag{3.45}$$
if \( \tau \leq \tau_0 \). Noting that \( \zeta_u^0 = 0 \), then we have

\[
\|\zeta_u^n\| \leq C(h^{k+1} + h^k \tau^{3/2}), \quad \forall n \tau \leq T.
\] 

(3.46)

Before arriving at the final error estimate, we need to verify that the a priori assumption (3.32) is reasonable. We will use the method of induction, along the similar argument as [21]. Since \( \zeta_u^0 = 0 \), the approximation property (3.28a) implies \( \|e_u^0\|_\infty \leq C_0h \), where \( C_0 \) only depends on the smoothness of the initial solution \( U_0(x) \). Also, Lemma 3.5 shows \( \|\xi_u,0,\ell\| \leq Ch^{k+1} \tau_1^{1/2} \) for \( \ell = 1, 2, 3 \), then by the triangle inequality, the inverse inequality (2.4b) and the approximation property (3.28a) we have

\[
\|e_u^0,\ell\|_\infty \leq \mu h^{-1/2} \|\xi_u^0,\ell\| + \|\eta_u^0,\ell\|_\infty \leq C \mu h^{k+1/2} \tau^{1/2} + Ch^{k+1/2} \leq C_0h,
\]

for \( k > 1 \). Assuming \( \|e_u^m,\ell\|_\infty \leq Ch^{k+1/2} \) holds for \( m \), we can show it also holds for \( m + 1 \). From (3.40) we know \( \|\xi_u^{m+1}\| \leq C(h^{k+1} + h^k \tau^{3/2}) \leq Ch^2 \), if \( k \geq 2 \). Hence

\[
\|e_u^{m+1}\|_\infty \leq \mu h^{-1/2} \|\xi_u^{m+1}\| + \|\eta_u^{m+1}\|_\infty \leq C \mu h^{3/2} + Ch^{k+1/2} \leq Ch^{3/2},
\]

and for \( \ell = 1, 2, 3 \), by Lemma 3.5 we can also deduce that

\[
\|e_u^{m+1,\ell}\|_\infty \leq Ch^{3/2}.
\]

Apparently there exists a positive constant \( h_0 < 1 \) such that \( Ch^{1/2} \leq C_0 \), if \( h \leq h_0 \), consequently we get \( \|e_u^{m+1,\ell}\| \leq C_0h \), for \( \ell = 0, 1, 2, 3 \). Thus the assumption (3.32) is reasonable.

As a consequence, by Young’s inequality we have

\[
\|\xi_u^n\| \leq C(h^{k+1} + h^{2k} + \tau^3) \leq C(h^{k+1} + \tau^3),
\]

(3.47)

if \( h \leq h_0 \). Finally, owing to (3.24), (3.28a), (3.28b) and the triangle inequality we get the main error estimate stated in Theorem 3.2.

Remark 3. We can also prove the optimal error accuracy for the first and second order schemes (3.1) and (3.2), along the similar argument shown in this section, but it is not necessary to make the a priori assumption (3.32), since in the lower order IMEX schemes, the number of explicit stages is the same as the number of the implicit stages [14], hence no trouble term like \( Z_2 \) (see (3.42)) will appear in the analysis. The optimal error accuracy can be obtained for arbitrary \( k \geq 1 \) in the first and second order case, under the same temporal condition as Theorem 3.2.

4. Multi-step IMEX LDG schemes

In this section, we will study the stability property of multi-step IMEX schemes coupled with the LDG spatial discretization. The error estimates can be carried out similarly as the RK type IMEX LDG schemes, but we skip the analysis and only give some numerical tests in the next section. We would like to consider the second and third order schemes given by Gottlieb and Wang [14]. Similar results can also be obtained for the fourth order scheme given in [14], but we omit the details to save space.
4.1. Second order

First we study the second order multi-step IMEX scheme, which coupled with LDG method has the following form: for any \((v, r) \in V_h \times V_h\), we have

\[
(u^{n+1}, v) = (u^n, v) + \frac{3}{2} \tau \mathcal{H}(f(u^n), v) - \frac{1}{2} \tau \mathcal{H}(f(u^{n-1}), v)
+ \frac{1}{4} \tau \mathcal{L}(q^{n-1}, v) + \frac{3}{4} \tau \mathcal{L}(q^{n+1}, v).
\]  

(4.1a)

for \(n \geq 1\). As for the auxiliary variable \(q^n\), we have the same variational form as before:

\[
(q^n, r) = \mathcal{K}(u^n, r), \quad \forall n.
\]  

(4.1b)

**Proposition 4.1.** There exist positive constant \(\tau_0\) independent of \(h\), such that if \(\tau \leq \tau_0\), then the solution of the scheme (4.1) satisfies

\[
\|u^{n+1}\|^2 + \tau \sum_{j=1}^{n} \|q^{j+1}\|^2 \leq C \sum_{j=0}^{1} (\|u^j\|^2 + \tau \|q^j\|^2),
\]  

(4.2)

where the bounding constant \(C\) is independent of \(h\) and \(\tau\).

**Proof.** By taking \(v = u^{n+1}\) in (4.1a), we get

\[
\frac{1}{2} \|u^{n+1}\|^2 + \frac{1}{2} \|u^{n+1} - u^n\|^2 - \frac{1}{2} \|u^n\|^2 = T_1 + T_2,
\]

where \(T_1\) and \(T_2\) are related to the \(\mathcal{H}\) and \(\mathcal{L}\) operators respectively, namely,

\[
T_1 = \frac{3}{2} \tau \mathcal{H}(f(u^n), u^{n+1}) - \frac{1}{2} \tau \mathcal{H}(f(u^{n-1}), u^{n+1}),
\]

\[
T_2 = \frac{1}{4} \tau \mathcal{L}(q^{n-1}, u^{n+1}) + \frac{3}{4} \tau \mathcal{L}(q^{n+1}, u^{n+1}).
\]

Each term can be estimated easily. Noticing the non-positive property (see Lemma 2.4), a simple manipulation yields

\[
T_1 = \frac{3}{2} \tau \mathcal{H}(f(u^n), u^{n+1}) - \frac{1}{2} \tau \mathcal{H}(f(u^{n-1}), u^{n+1})
= \tau \mathcal{H}(f(u^{n+1}), u^{n+1}) - \tau \mathcal{D}(u^{n+1}, u^n; u^{n+1}) + \frac{1}{2} \tau \mathcal{D}(u^n, u^{n-1}; u^{n+1})
\leq \tau \mathcal{D}(u^{n+1}, u^n; u^{n+1}) + \frac{1}{2} \tau \mathcal{D}(u^n, u^{n-1}; u^{n+1}).
\]

By property (3.12) we can derive

\[
T_2 = -\frac{1}{4} \tau(q^{n+1}, q^{n-1}) - \frac{3}{4} \tau \|q^{n+1}\|^2.
\]
As a result, summing in time gives rise to
\[
\frac{1}{2} \|u^{n+1}\|^2 - \frac{1}{2} \|u^n\|^2 + \sum_{j=1}^{n} \|u^{j+1} - u^j\|^2 + 3\tau \sum_{j=1}^{n} \|q^{j+1}\|^2
\leq -\tau R_{\text{HSS}}(u^{j+1}, u^n; u^{j+1}) + \tau \sum_{j=1}^{n} R_{\text{HSS}}(u^{j}, u^{j-1}; u^{j+1}) - \frac{1}{4} \tau \sum_{j=1}^{n} (q^{j+1}, q^{j-1}).
\]

Exploiting Assumptions 2.1 and Lemma 2.3 for the first two terms, for example
\[
|D(u^{j+1} - u^j, u^{j+1})| \leq C_f \|u^{j+1} - u^j\| (\|u^{j+1}\| + \sqrt{\mu h^{-1}} \|u^{j+1}\|)
\leq \frac{C_f C_m}{\sqrt{d}} \|u^{j+1} - u^j\| q^{j+1},
\]
and applying the Cauchy-Schwarz inequality for the third term, we get
\[
R_{\text{HSS}} \leq \frac{C_f C_m}{\sqrt{d}} \tau \sum_{j=1}^{n} \|u^{j+1} - u^j\| q^{j+1} + \frac{C_f C_m}{2\sqrt{d}} \tau \sum_{j=1}^{n} \|u^{j} - u^{j-1}\| q^{j+1}
\leq \frac{1}{4} \tau \sum_{j=1}^{n} \|q^{j+1}\| q^{j-1}.
\]

Then the Young’s inequality leads to
\[
R_{\text{HSS}} \leq 2\varepsilon \tau \sum_{j=1}^{n} \|q^{j+1}\|^2 + \frac{C_f^2 C_m^2}{4\varepsilon d} \tau \sum_{j=1}^{n} \|u^{j+1} - u^j\|^2 + \frac{C_f^2 C_m^2}{16\varepsilon d} \tau \sum_{j=1}^{n} \|u^{j} - u^{j-1}\|^2
\leq \frac{1}{8} \tau \sum_{j=1}^{n} (\|q^{j+1}\|^2 + \|q^{j-1}\|^2),
\]
for arbitrary positive constant \(\varepsilon\). Consequently, if we take \(\varepsilon = \frac{1}{8}\), we have
\[
R_{\text{HSS}} \leq \frac{1}{2} \tau \sum_{j=1}^{n} \|q^{j+1}\|^2 + \frac{5 C_f^2 C_m^2}{2d} \tau \sum_{j=1}^{n} \|u^{j+1} - u^j\|^2
\leq \frac{C_f^2 C_m^2}{2d} \tau \|u^n - u^0\|^2 + \frac{1}{8} \tau (\|q^n\|^2 + \|q^0\|^2).
\]

Hence if \(\frac{5 C_f^2 C_m^2}{2d} \tau \leq \frac{1}{2}\), i.e., \(\tau \leq \tau_0 = \frac{d}{5 C_f^2 C_m^2}\), then we obtain \(4.2\). \(\blacksquare\)

4.2. Third order

For arbitrary \((v, r) \in V_h \times V_h\), the LDG scheme with the third order multi-step IMEX time marching method has the following variation form:
\[
(u^{n+1}, v) = (u^n, v) + \frac{23}{12} \tau H(f(u^n), v) - \frac{4}{3} \tau H(f(u^{n-1}), v) + \frac{5}{12} \tau H(f(u^{n-2}), v)
\leq \frac{2}{3} \tau L(q^{n+1}, v) + \frac{5}{12} \tau L(q^{n-1}, v) - \frac{1}{12} \tau L(q^{n-3}, v),
\]
(4.4)
for \( n \geq 3 \), and for \( q^n \), the variational form is the same as before.

**Proposition 4.2.** Under the condition of Proposition 4.1, the solution of the scheme (4.4) satisfies

\[
\|u^{n+1}\|^2 + \tau \sum_{j=3}^{n} \|q^{j+1}\|^2 \leq C \sum_{j=0}^{3} (\|u^j\| + \|q^j\|^2). \tag{4.5}
\]

**Proof.** Taking \( v = u^{n+1} \) in (4.4) we obtain

\[
\frac{1}{2} \|u^{n+1}\|^2 + \frac{1}{2} \|u^{n+1} - u^n\|^2 - \frac{1}{2} \|u^n\|^2 = T_3 + T_4, \tag{4.6}
\]

where after some manipulation and by Lemma 2.3 we have

\[
T_3 = \tau H(f(u^{n+1}), u^{n+1}) - \tau D(u^{n+1}, u^n; u^{n+1}) + \frac{11}{12} \tau D(u^n, u^{n-1}; u^{n+1})
\]
\[
- \frac{5}{12} \tau D(u^{n-1}, u^{n-2}; u^{n+1}) \]
\[
\leq \tau [-D(u^{n+1}, u^n; u^{n+1}) + \frac{11}{12} D(u^n, u^{n-1}; u^{n+1}) - \frac{5}{12} D(u^{n-1}, u^{n-2}; u^{n+1})],
\]

and from the property (3.12) we can get

\[
T_4 = \tau L\left(\frac{2}{3} q^{n+1} + \frac{5}{12} q^{n-1} - \frac{1}{12} q^{n-3}, u^{n+1}\right)
\]
\[
- \frac{5}{12} \tau \|q^{n+1}\|^2 - \frac{5}{12} \tau (q^{n+1}, q^{n-1}) + \frac{1}{12} \tau (q^{n+1}, q^{n-3}).
\]

Summing in time leads to

\[
\frac{1}{2} \|u^{n+1}\|^2 - \frac{1}{2} \|u^n\|^2 + \frac{1}{2} \sum_{j=3}^{n} \|u^{j+1} - u^j\|^2 + \frac{2}{3} \tau \sum_{j=3}^{n} \|q^{j+1}\|^2
\]
\[
\leq \tau \sum_{j=3}^{n} [-D(u^{j+1}, u^j; u^{j+1}) + \frac{11}{12} D(u^j, u^{j-1}; u^{j+1}) - \frac{5}{12} D(u^{j-1}, u^{j-2}; u^{j+1})]
\]
\[
- \frac{5}{12} \tau \sum_{j=3}^{n} (q^{j+1}, q^{j-1}) + \frac{1}{12} \tau \sum_{j=3}^{n} (q^{j+1}, q^{j-3}) = RHS. \tag{4.7}
\]

Proceeding the similar analysis as in Subsection 4.1 we obtain

\[
RHS \leq \frac{C_f C_D \tau}{\sqrt{d}} \sum_{j=3}^{n} (\|u^{j+1} - u^j\| + \|u^j - u^{j-1}\| + \|u^{j-1} - u^{j-2}\|) \|q^{j+1}\|
\]
\[
+ \frac{5}{12} \tau \sum_{j=3}^{n} \|q^{j+1}\| \|q^{j-1}\| + \frac{1}{12} \tau \sum_{j=3}^{n} \|q^{j+1}\| \|q^{j-3}\|.
\]
A simple use of the Young’s inequality yields
\[
\text{RHS} \leq \frac{1}{8} \tau \sum_{j=3}^{n} \|q^{j+1}\|^2 + \frac{5}{24} \tau \sum_{j=3}^{n} (\|q^{j+1}\|^2 + \|q^{j-1}\|^2) \\
+ \frac{1}{24} \tau \sum_{j=3}^{n} (\|q^{j+1}\|^2 + \|q^{j-3}\|^2) \\
+ \frac{6C^2C^2}{d} \mu \tau \sum_{j=3}^{n} (\|u^{j+1} - u^j\|^2 + \|u^j - u^{j-1}\|^2 + \|u^{j-1} - u^{j-2}\|^2).
\]

As a consequence,\[
\text{RHS} \leq \frac{5}{8} \tau \sum_{j=3}^{n} \|q^{j+1}\|^2 + \frac{18C^2C^2}{d} \mu \tau \sum_{j=3}^{n} \|u^{j+1} - u^j\|^2 \\
+ \frac{12C^2C^2}{d} \mu \tau (\|u^3 - u^2\|^2 + \|u^2 - u^1\|^2) + \frac{1}{4} \tau \sum_{j=0}^{3} \|q^j\|^2.
\]
So if \( \frac{18C^2C^2}{d} \mu \tau \leq \frac{1}{4} \), i.e., \( \tau \leq \tau_0 = \frac{d}{36C^2C^2 \mu} \), then we get (4.5). \( \square \)

**Remark 4.** Along the similar line as before, we can also obtain the error estimates to these fully discrete with the IMEX multi-step time-marching.

### 5. Numerical experiments

The purpose of this section is to numerically validate the stability and error accuracy for the Runge-Kutta IMEX LDG schemes (3.2), (3.3) and the multi-step IMEX LDG schemes (4.1), (4.4). For the third order Runge-Kutta IMEX LDG scheme (3.3), we take the parameter \( \alpha_1 = -0.35 \) as the choice in [3].

In all the experiments, we take the finite element space as piecewise linear polynomials for the second order schemes (3.2) and (4.1), and piecewise quadratic polynomials for the third order schemes (3.3) and (4.4), respectively. In the implementation of the second order multi-step IMEX LDG scheme (4.1), we adopt the first order IMEX RK LDG scheme (3.1) to compute the solution at the first time level. And to implement the third order multi-step IMEX LDG scheme (4.4), we use the second order IMEX RK LDG scheme (3.2) to compute the solutions at the first three time levels.

We will take the Burgers equation
\[
U_t + \left( \frac{U^2}{2} \right)_x = dU_{xx} + g(x,t), \quad (x,t) \in Q_T = (-\pi, \pi) \times (0, T], \quad (5.1a)
U(x,0) = U_0(x), \quad (x,t) \in \Omega = (-\pi, \pi), \quad (5.1b)
\]
as an example to test the stability of the four schemes. We will consider two cases:
Case (i): \( U_0(x) = \sin(x), g(x, t) = \cos(x + t)(1 + \sin(x + t)) + d \sin(x + t), \) the exact solution is \( u(x, t) = \sin(x + t). \)

Case (ii): \( U_0(x) = \frac{1}{2} \sin(x), g(x, t) = \frac{1}{2} \cos(x + t)(1 + \frac{1}{2} \sin(x + t)) + \frac{1}{2} d \sin(x + t), \) the exact solution is \( u(x, t) = \frac{1}{2} \sin(x + t). \)

Table 2: The maximum time step \( \tau_0 \) to ensure that the \( L^2 \)-norm is bounded with time for the schemes.

<table>
<thead>
<tr>
<th>scheme</th>
<th>Case (i)</th>
<th>Case (ii)</th>
</tr>
</thead>
<tbody>
<tr>
<td>second order RK (3.2)</td>
<td>0.183</td>
<td>0.717</td>
</tr>
<tr>
<td>third order RK (3.4)</td>
<td>0.497</td>
<td>1.228</td>
</tr>
<tr>
<td>second order multi-step (4.1)</td>
<td>0.020</td>
<td>0.045</td>
</tr>
<tr>
<td>third order multi-step (4.4)</td>
<td>0.057</td>
<td>0.689</td>
</tr>
</tbody>
</table>

Table 2 lists the maximum time step \( \tau_0 \) which can be chosen to ensure the stability of the schemes (in the sense that the \( L^2 \) norm of \( u \) is bounded with time) for solving problem (5.1) on uniform meshes, with mesh size \( h = 2\pi/N \), where \( N \) is the number of cells. In this test, we take \( N = 640 \) and the final computing time is \( T = 5000 \). We can observe the similar result as the linear case, i.e., for all the four schemes, \( \tau_0 \) is larger if the diffusion coefficient \( d \) is bigger, but it is smaller when the flow velocity is bigger. Besides, we can find that for the same type schemes, the third order scheme admits larger time step than the second order scheme, and the IMEX RK schemes admit larger time step than the multi-step type schemes.

Next we will test the following three examples to verify the orders of accuracy of the four schemes.

**Example 1.**

\[
U_t + \left( \frac{U^2}{2} \right)_x = dU_{xx} + g(x, t), \quad (x, t) \in Q_T = (-\pi, \pi) \times (0, T], \quad (5.2a)
\]

\[
U(x, 0) = \sin(x), \quad x \in \Omega = (-\pi, \pi), \quad (5.2b)
\]

where \( g(x, t) = \frac{1}{2} e^{-2dt} \sin(2x). \)

**Example 2.**

\[
U_t + \left( \frac{U^3}{3} \right)_x = dU_{xx} + g(x, t), \quad (x, t) \in Q_T = (-\pi, \pi) \times (0, T], \quad (5.3a)
\]

\[
U(x, 0) = \sin(x), \quad x \in \Omega = (-\pi, \pi), \quad (5.3b)
\]

where \( g(x, t) = e^{-3dt} \sin^2(x) \cos(x). \)

**Example 3.**

\[
U_t + \left( e^U \right)_x = dU_{xx} + g(x, t), \quad (x, t) \in Q_T = (-\pi, \pi) \times (0, T], \quad (5.4a)
\]

\[
U(x, 0) = \sin(x), \quad x \in \Omega = (-\pi, \pi), \quad (5.4b)
\]
where \( g(x,t) = e^{-dt} \sin(x) e^{-dt} \cos(x) \).

The exact solutions of (5.2), (5.3) and (5.4) are all

\[
U(x,t) = e^{-dt} \sin(x).
\]  

(5.5)

In the following tests, we will take \( d = 0.5 \), and the final computing time is \( T = 10 \).

Tables 3-6 are the \( L^2 \) errors and orders of accuracy for the IMEX RK LDG schemes (3.2), (3.3) and the multi-step IMEX LDG schemes (4.1), (4.4) for solving the above three examples on nonuniform meshes, respectively. The nonuniform meshes are obtained by randomly perturbing each node in the uniform mesh by up 20%. We take \( \tau = h \) in all the tests. We can clearly observe the designed orders of accuracy from these tables.

6. Concluding remarks

We consider several specific implicit-explicit time marching methods coupled with the LDG schemes for solving nonlinear convection-diffusion problems with periodic boundary conditions. Both Runge-Kutta type and multi-step type IMEX schemes are considered. By the aid of energy techniques, we prove that the corresponding IMEX LDG schemes are stable if \( \tau \leq \tau_0 \), where the constant

$\tau_0$ is independent of the mesh size $h$. We also present optimal error estimates in both space and time, for the third order IMEX Runge-Kutta scheme coupled with the LDG spatial discretization, under the same temporal condition, if a general monotone numerical flux is adopted.

7. Appendix

In this Appendix, we will give the proof of (4.42). Before doing that, we will give some preliminary work. First we follow [21] to introduce an important quantity

$$\alpha(\hat{f}; p) \equiv \alpha(\hat{f}; p^-, p^+) \equiv \begin{cases} [p]^{-1}(f(\bar{p}) - \hat{f}(p)) & \text{if } [p] \neq 0, \\ |f'(\bar{p})| & \text{if } [p] = 0, \end{cases} \quad (7.1)$$

for any $p \in H^1(T_h)$, to measure the viscosity provided by the numerical flux, where $\bar{p} = \frac{p^- + p^+}{2}$. From the Lipschitz continuity of $\hat{f}$, we can get that $\alpha(\hat{f}; p)$ is bounded for any $(p^-, p^+) \in \mathbb{R}^2$. We would like to use the notation $C_f$ to denote the bound of $\alpha(\hat{f}; p)$. In addition, we would like to assume

$$|\alpha(\hat{f}; p_1) - \alpha(\hat{f}; p_2)| \leq C_f(|\bar{p}_1 - \bar{p}_2| + ||p_1|| + ||p_2||), \quad (7.2)$$
for arbitrary $p_1, p_2 \in H^1(T_h)$. It can be verified that this assumption is valid for several well known monotone numerical flux, such as the upwind flux, the Godunov flux and the Lax-Friedrichs flux.

Next we would like to follow [21] to divide the operator $\mathcal{D}(U, u; v)$ (here and below, we omit the superscript $n, \ell$ for simplicity of notation) into three parts, namely,

$$\mathcal{D}(U, u; v) = \mathcal{H}^{lin}(f'(U); e_u, v) + \mathcal{H}^{nls}(e_u; v) + \mathcal{V}(u; v), \quad (7.3)$$

where

$$\mathcal{H}^{lin}(f'(U); w, v) = \sum_{j=1}^{N} \left[ (f'(U)w, v_x)_j + (f'(U)\bar{w}[v])_{j-\frac{1}{2}} \right], \quad (7.4a)$$

$$\mathcal{H}^{nls}(e_u; v) = \sum_{j=1}^{N} \left[ (T_{int}(e_u), v_x)_j + (T_{brly}(e_u)[v])_{j-\frac{1}{2}} \right], \quad (7.4b)$$

$$\mathcal{V}(u; v) = \sum_{j=1}^{N} (f(\bar{u}) - \hat{f}(u))[v])_{j-\frac{1}{2}} = \sum_{j=1}^{N} (\alpha(\hat{f}; u)[v])[v])_{j-\frac{1}{2}}. \quad (7.4c)$$

Here

$$T_{int}(e_u) = f(U) - f(u) - f'(U)e_u, \quad (7.5a)$$

$$T_{brly}(e_u) = f(U) - f(\bar{u}) - f'(U)\bar{e}_u. \quad (7.5b)$$

are the nonlinear part of $f(\cdot)$ in the interior element and on the element boundary, respectively.

**Lemma 7.1.** For arbitrary $w, v \in V_h$, we have

$$|\mathcal{H}^{lin}(f'(U); w, v)| \leq C_f(\|w\| + \|w_x\| + \sqrt{\mu h^{-1}}[w])\|v\|, \quad (7.6)$$

$$|\mathcal{H}^{nls}(e_u; v)| \leq C_f h^{-1}\|e_u\|_\infty(\|\xi_u\| + h^{k+1})\|v\|. \quad (7.7)$$

**Proof.** By (7.4a), we integrate by parts to obtain

$$\mathcal{H}^{lin}(f'(U); w, v) = \sum_{j=1}^{N} \left[ -(f'(U)xw, v)_j - (f'(U)xw, v)_j - (f'(U)x\bar{v}[w])_{j-\frac{1}{2}} \right].$$

From assumptions (3.21) and (3.25), we know that $|f'(U)|$ and $|f'(U)x| = |f''(U)U_x|$ are all uniformly bounded, we still denote the bound of them by $C_f$. By a simple use of the Cauchy-Schwarz inequality and the inverse inequality (2.4c) we get (7.6).

The conclusion (7.7) is almost the same as that in [21], so we omit the detailed proof. $\square$
In the following we take the term \( Z = \tau(D(U^{n,2}, u^{n,2}; v) - D(U^{n,1}, u^{n,1}; v)) \) as a typical term to give the estimate for \( Z_2 \), here and below \( v = \mathbb{E}_t \xi^n \). It is a little tricky to get optimal error estimate by considering the difference in this form. From (7.8) we have

\[
Z = Z^{lin}_\xi - Z^{lin}_\eta + Z^{nls} + Z^{vis},
\]

where

\[
\begin{align*}
Z^{lin}_\xi &= \tau \mathcal{H}^{lin}(f'(U^{n,2}); \xi^{n,2}_u, v) - \tau \mathcal{H}^{lin}(f'(U^{n,1}); \xi^{n,1}_u, v), \\
Z^{lin}_\eta &= \tau \mathcal{H}^{lin}(f'(U^{n,2}); \eta^{n,2}_u, v) - \tau \mathcal{H}^{lin}(f'(U^{n,1}); \eta^{n,1}_u, v), \\
Z^{nls} &= \tau \mathcal{H}^{nls}(e^{n,2}_u; v) - \tau \mathcal{H}^{nls}(e^{n,1}_u; v), \\
Z^{vis} &= \tau \mathcal{V}(u^{n,2}; v) - \tau \mathcal{V}(u^{n,1}; v).
\end{align*}
\]

We will estimate these terms one by one. First it follows from (7.6) that

\[
|Z^{lin}_\xi| \leq C_f \tau \sum_{\ell=1}^2 (\|\xi^{n,\ell}_u\| + \|\xi^{n,\ell}_u\|_x + \sqrt{\mu h^{-1}}\|\xi^{n,\ell}_u\|_\tau)v\|
\]

\[
\leq C_f \tau \sum_{\ell=1}^2 \|\xi^{n,\ell}_u\|_\tau v + C_f C_a \tau^2 \sum_{\ell=1}^2 (\|\xi^{n,\ell}_q\| + \|\eta^{n,\ell}_q\|)\|v\|
\]

\[
\leq \frac{\tau}{2}(\|\xi^{n,1}_u\|^2 + \|\xi^{n,2}_u\|^2) + \frac{\varepsilon}{2}(\|\xi^{n,1}_q\|^2 + \|\xi^{n,2}_q\|^2 - 2\xi^{n,1}_q)^2
\]

\[
+ \left(C^2_f + \frac{C_f^2 C_a^2}{d}\right) \|\eta\|^2 + Ch^{2k+2}\tau,
\]

(7.8)

for arbitrary \( \varepsilon > 0 \), where the second inequality holds by (3.30) and the last one by (3.28a), the Young’s inequality and the triangle inequality. Notice that

\[
Z^{lin}_\eta = \tau \mathcal{H}^{lin}(f'(U^{n,2}) - f'(U^{n,1}); \eta^{n,2}_u, v) + \tau \mathcal{H}^{lin}(f'(U^{n,1}); \eta^{n,2}_u - \eta^{n,1}_u, v).
\]

From (7.27a) we have

\[
A_1 \leq \tau \max |f'(U^{n,2}) - f'(U^{n,1})|(\mu h^{-1}\|\eta^{n,2}_u\| + \sqrt{\mu h^{-1}}\|\eta^{n,2}_u\|_\tau)v\|
\]

\[
A_2 \leq \tau \max |f'(U^{n,1})|(\mu h^{-1}\|\eta^{n,2}_u - \eta^{n,1}_u\| + \sqrt{\mu h^{-1}}\|\eta^{n,2}_u - \eta^{n,1}_u\|_\tau)v\|
\]

where we have used the Cauchy-Schwarz inequality, the inverse inequalities (2.4a) and (2.4c). Then from (3.28) and the fact that \( |f'(U^{n,2}) - f'(U^{n,1})| \leq C_f|U^{n,2} - U^{n,1}| \leq C_f\tau \), we can get

\[
A_1, A_2 \leq C_f \tau^2 h^k\|v\|.
\]

Hence the Young’s inequality yields

\[
Z^{lin}_\eta \leq C_f \tau^2 h^k + \frac{\varepsilon}{2}\|v\|^2,
\]

(7.9)
for arbitrary $\varepsilon > 0$.

By applying (7.7), the assumption (3.32) and the Young’s inequality we have

$$Z^{vis} \leq C_f \tau \sum_{t=1}^{2} h^{-1} \| e^{n,t}_u \|_{\infty} (\| \xi^{n,t}_u \| + h^{k+1}) \| v \|$$

$$\leq C_f C_0 \tau \sum_{t=1}^{2} (\| \xi^{n,t}_u \| + h^{k+1}) \| v \|$$

$$\leq \frac{\tau}{2} (\| \xi^{n,1}_u \|^2 + \| \xi^{n,2}_u \|^2) + C_f^2 C_0^2 \tau \| v \|^2 + C h^{2k+2}. \quad (7.10)$$

At last we estimate the term $Z^{vis}$. From (7.36) and the fact that $[U^{n,\ell}]_{j-\frac{1}{2}} = 0$, we have

$$Z^{vis} = \tau \sum_{j=1}^{N} \left( \alpha(\hat{f}; u^{n,2})[e^{n,2}_u][v] - \alpha(\hat{f}; u^{n,1})[e^{n,1}_u][v] \right)_{j-\frac{1}{2}} = Z^{vis}_\xi - Z^{vis}_\eta,$$

where the property of $\alpha(\cdot, \cdot)$ plays an important role, since

$$Z^{vis}_\xi = \tau \sum_{j=1}^{N} \left( \alpha(\hat{f}; u^{n,2})[\xi^{n,2}_u][v] - \alpha(\hat{f}; u^{n,1})[\xi^{n,1}_u][v] \right)_{j-\frac{1}{2}},$$

$$Z^{vis}_\eta = \tau \sum_{j=1}^{N} \left( \alpha(\hat{f}; u^{n,2})[\eta^{n,2}_u][v] - \alpha(\hat{f}; u^{n,1})[\eta^{n,1}_u][v] \right)_{j-\frac{1}{2}}$$

$$= \tau \sum_{j=1}^{N} \left( \alpha(\hat{f}; u^{n,2}) - \alpha(\hat{f}; u^{n,1}) \right)[\eta^{n,2}_u][v] + \alpha(\hat{f}; u^{n,1})[\eta^{n,2}_u - \eta^{n,1}_u][v].$$

A simple use of the Cauchy-Schwarz inequality and the inverse inequality yields

$$Z^{vis}_\xi \leq C_f \tau \sqrt{\mu h^{-1}} \sum_{t=1}^{2} \| e^{n,t}_u \| \leq \frac{C_f C_n}{\sqrt{d}} \tau \sum_{t=1}^{2} (\| \xi^{n,t}_u \| + \| \eta^{n,t}_u \|) \| v \|$$

$$\leq C_f C_0 \tau \sum_{t=1}^{2} \| \xi^{n,t}_u \|^2$$

$$+ \frac{\tau}{2} (\| \xi^{n,1}_u \|^2 + \| \xi^{n,2}_u \|^2) + \frac{C_f^2 C_0^2}{d} \tau \| v \|^2 + C h^{2k+2},$$

where the second inequality follows from (3.36) and the last inequality holds by (3.32), the Young’s inequality and the triangle inequality.

From the assumptions (7.2) and (3.32) we have

$$|\alpha(\hat{f}; u^{n,2}) - \alpha(\hat{f}; u^{n,1})| \leq C_f (|\tilde{w}^{n,2} - \tilde{w}^{n,1}| + |u^{n,2}| + |u^{n,1}|)$$

$$\leq C_f (|U^{n,2} - U^{n,1}| + |\tilde{e}^{n,2}_u| + |\tilde{e}^{n,1}_u| + |\tilde{e}^{n,2}_u| + |\tilde{e}^{n,1}_u|)$$

$$\leq C_f (\tau + \| e^{n,1}_u \|_{\infty} + \| e^{n,2}_u \|_{\infty}) \leq C_f (\tau + C_0 h),$$

$28$
where the second inequality holds by the triangle inequality and the fact that $U^{n,\ell} = U^{n,\ell}$ and $[U^{n,\ell}] = 0$ for $\ell = 1, 2$ at the element interface. So Cauchy-Schwarz inequality, the inverse inequality (2.4c) and (3.28) leads to

$$Z_{\eta}^{vis} \leq C_{f} \tau (\| \xi_{n,1}^{u} \|^{2} + \| \xi_{n,2}^{u} - 2 \xi_{n,1}^{u} \|^{2}) \leq \frac{\varepsilon}{2} \| v \|^{2} + C(h^{2k+2} \tau^{2} + h^{2k} \tau^{4}),$$

for arbitrary $\varepsilon > 0$. As a result,

$$Z_{\eta}^{vis} \leq \frac{\varepsilon}{2} \tau (\| \xi_{n,1}^{u} \|^{2} + \| \xi_{n,2}^{u} - 2 \xi_{n,1}^{u} \|^{2}) \leq \frac{\varepsilon}{2} C_{f}^{2} \tau^{2} + \frac{\varepsilon}{2} C_{f}^{2} \tau^{4} \| v \|^{2} + C(h^{2k+2} \tau^{2} + h^{2k} \tau^{4}).$$

Combining the above estimates together, we get

$$Z \leq \tau (\| \xi_{n,1}^{u} \|^{2} + \| \xi_{n,2}^{u} \|^{2}) + \varepsilon \tau (\| \xi_{n,1}^{u} \|^{2} + \| \xi_{n,2}^{u} - 2 \xi_{n,1}^{u} \|^{2})$$

$$+ (C_{f}^{2} \tau^{2} + C_{f}^{2} \tau + \frac{C_{f}^{2} \tau^{4}}{d}) \| v \|^{2} + C(h^{2k+2} \tau^{2} + h^{2k} \tau^{4}).$$

The similar result can be obtained for $\tau (D(U^{n,3}, u^{n,3}; v) - D(U^{n,1}, u^{n,1}; v))$. Thus we are led to
